The molecular structure has been derived from electron-diffraction data by Danford and Livingston (5) and from microwave data by Sheridan and Gordy (6) and Thomas et al. (7). These studies are in substantial agreement except for a difference of about 0.04 Å in the C-C bond distance. We adopt the results of Thomas et al. (7) since they are based on data for several isotopic species. Principal moments of inertia are $I_A = 14.676 \times 10^{-39}$ and $I_B = I_C = 28.482 \times 10^{-39} \text{ g cm}^2$. Vibrational frequencies are taken from the assignments of Edgell and Potter (8). All values except ν_9 are from infrared spectra of the vapor phase. Raman spectra of the liquid provide ν_9 and confirm the infrared data. Similar assignments have been given by Janz and Wait (9) based on spectra of Wait and Janz (10).

Pace and Bobka (11) used low temperature calorimetric data to derive the entropy of the ideal gas at the normal boiling point of 205.47 K. The experimental value of 65.01 ± 0.2 gbbbs/mol is in good agreement with 65.03 gbbbs/mol obtained from this table. The largest uncertainty in Cp° and S° probably arises from neglect of anharmonicity and rotational distortion. Uncertainty in the entropy is estimated to vary from 0.1 to 0.5 gbbbs/mol over the range 300 to 1000°K. Discussions of the neglect of anharmonicity are given on the tables for CClF₃(g) and CF₄(g).

TETRAFLUOROETHYLENE (C₂F₄)

(IDEAL GAS) GFW = 100.0159

Point Group D_{2h}ΔH₀^a = -156.6 ± 0.7 kcal/molS_{298.15} = 71.678 ± 0.1 gibbs/molΔH_{298.15} = -157.4 ± 0.7 kcal/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω ₁ , cm ⁻¹	ω ₂ , cm ⁻¹	ω ₃ , cm ⁻¹	ω ₄ , cm ⁻¹
1072 (1)	1340 (1)	1337 (1)	
778 (1)	551 (1)	218 (1)	
394 (1)	406 (1)	1186 (1)	
190 (1)	508 (1)	558 (1)	

Bond Distance: C-F = 1.313 Å C-C = 1.313 Å

Bond Angle: F-C-F = 114°

Product of the Moments of Inertia: I_AI_BI_C = 1.5877 × 10⁻¹¹³ g³ cm⁶

Heat of Formation

The selected value is obtained from least squares, simultaneous adjustment of the heats of formation of CF₃, CF₃X (X = H, Cl, Br, I, CF₃) and C₂F₄. Details of the input data and the adjustment are given in (1). In this case, the selected ΔH^a corresponds to the weighted average of three calorimetric studies (2, 3) which may be reduced to the following:

Reference	Reaction	ΔH _{298.15} kcal/mol	ΔH _{298.15} kcal/mol
(2)	C ₂ F ₄ (g) + CF ₄ (g) + C(graphite)	-65.4 ± 0.5	-157.6 ± 0.6
(2)	C ₂ F ₄ (g) + 2H ₂ (g) + 4HF(50 H ₂ O) + 2C(graphite)	-150.9 ± 1.2	-156.2 ± 1.3
(3)	C ₂ F ₄ (g) + 4Na(c) + 4NaF(c) + 2C(graphite)	-392.9 ± 1.3	-157.2 ± 1.4

Amorphous carbon was formed in all three calorimetric reactions and separate combustions were made to refer the observed product to the standard state of graphite. Other calorimetric studies (4, 5, 6) are omitted because of apparent uncertainties in the reductions to the standard-state reactions.

Heat Capacity and Entropy

The molecular structure has been derived from electron-diffraction data by Karle (7), Broun (8) and Young (9). The resulting structures differ in minor respects, particularly in the exact location of the two carbons. Values from Karle (7) are adopted since they are intermediate between the others. Values from Young (9) and Broun (8) correspond to changes of ± 2.4 in the product of the moments of inertia. Principal moments of inertia for the adopted structure are I_A = 15.30 × 10⁻³⁹, I_B = 25.46 × 10⁻³⁹ and I_C = 40.76 × 10⁻³⁹ g cm². Vibrational fundamentals are those selected by Shimanouchi (10) from the data of Mann (11), Honfils (12) and Nielsen (13).

Furukawa (14) reported low-temperature calorimetric data from which the ideal gas entropy may be derived as 64.54 ± 0.09 gibbs/mol at 197.53°K. The calculated entropy from this table is also 64.54 eu. The range in values of I_AI_BI_C corresponds to an entropy change of ± 0.022 eu.

Heat of Formation.

The heat of formation of C₂H(g) is not well established; however, we can place reliable upper and lower limits on the value.

T. L. Cottrell, "The Strengths of Chemical Bonds," 2nd Ed., Academic Press, New York, 1958, gives an upper limit for the C-H bond dissociation energy in acetylene, D(HCC-H) <121 kcal. This was obtained from the fact that ultraviolet light of 121 kcal/mol energy causes acetylene to form diacetylene and hydrogen; assuming that this process occurs through the CCH radical, the light energy is equated with D(HCC-H). This value of D(HCC-H) gives an upper limit for ΔH_f^o(CCH,g) <123 kcal/mol.

A lower limit for D(HCC-H) is obtained from a consideration of the C-H bond dissociation energies in ethylene and ethane, D(C₂H₅-H) = 105 kcal and D(C₂H₄-H) = 98 kcal. The heats of formation of the C₂H₅ and C₂H₄ radicals and their parent compounds are taken from S. W. Benson, J. Chem. Educ. 42, 502 (1965). The vibrational frequency of the C-H stretch increases steadily from ethane to ethylene and acetylene. Similarly we expect the bond strength to increase, and so D(HCC-H) >103 kcal; this yields ΔH_f^o(CCH,g) >105 kcal/mol.

F. H. Coates and R. C. Anderson, J. Am. Chem. Soc. 79, 1340 (1957), obtained several values for ΔH_f^o(CCH,g) from mass-spectroscopic measurements; their values range from 110 kcal/mol to 153 kcal/mol, but they chose to adopt 112 ± 3 kcal/mol.

Our adopted value of ΔH_f^o(CCH,g), 114 ± 7 kcal/mol, is 2 kcal smaller than that estimated by W. Tseng.

S. H. Bauer and M. Comperthwaite, J. Chem. Phys. 35, 1768 (1962).

Heat Capacity and Entropy.

The molecule is assumed to be linear; the bond lengths are assumed to be the same as in acetylene and were taken from L. E. Sutton, "Interatomic Distances Supplement," Special Publication No. 18, The Chemical Society, London, 1955.

The vibrational frequencies are those estimated by M. N. Flooster and T. B. Reed, J. Chem. Phys. 31, 66 (1959). It should be noted that the values of the free energy function given by Flooster and Reed are incorrect due to the neglect of the electronic contributions.

The electronic levels, X²Σ⁺ and A²Π⁺, were estimated by analogy with those of CN(g) which is isoelectronic; this assumption holds very well in the parent molecules HCC and HCN (D. Herzberg, "Electronic Spectra and Electronic Structure of Polyatomic Molecules," D. Van Nostrand Co., New York, 1966). The molecule C₂H₂⁺, which is also isoelectronic with CCH, is predicted to have a ²Π ground state by Herzberg, loc. cit.

Bond Distances: C-C = 1.204 Å C-H = 1.055 Å C-Cl = 1.637 Å

Bond Angles: Cl-C-C = 180° C-C-H = 180° σ = 1

Rotational Constant: B₀ = 0.188641 cm⁻¹

Heat of Formation

The value of $\Delta H_f^\circ = 51.1 \text{ kcal/mol}$ is calculated from the estimated $\Delta H_{298}^\circ = -53 \pm 10 \text{ kcal/mol}$ for $\text{HCCl}(\text{g}) + \text{Cl}_2(\text{g}) + \text{CHCl}_2\text{Cl}(\text{g})$, using $\Delta H_f^\circ(\text{HCCl}(\text{g})) = -1.86 \text{ kcal/mol}$ (1). The value of ΔH_{298}° is assumed to be the same as that for the reaction $\text{HCCl}(\text{g}) + \text{Cl}_2(\text{g}) + \text{CHCl}_2\text{Cl}(\text{g})$, using $\Delta H_f^\circ(\text{C}_2\text{H}_2, \text{g}) = 54.19 \text{ kcal/mol}$ (2) and $\Delta H_f^\circ(\text{CHCl}_2\text{Cl}, \text{g}) = 1.2 \text{ kcal/mol}$ (2).

Heat Capacity and Entropy

The linear molecular structure and bond distances were determined from the microwave spectrometrical studies by Tyler and Sheridan (3). Their results are in good agreement with those of Westenberg, Goldstein and Wilson (4). The principal moment of inertia is $1.48381 \times 10^{-38} \text{ g cm}^2$.

The vibrational frequencies were observed in the infrared spectra by Hunt and Wilson (5), and Richardson and Goldstein (6).

C-C = 1.138 Å

C-H = 1.053 Å

C-C-H = 180°

$\sigma = 1$

Bond Distances: C-F = 1.279 Å

Bond Angles: F-C-C = 180°

Rotational Constant: $B_0 = 0.323571 \text{ cm}^{-1}$

Heat of Formation

The heat of formation is estimated by assuming that the C-C bond strength is the average of those in C_2F_4 (113 kcal) and C_2H_2 (229 kcal). Combining the average value (171 kcal) with the heats of formation of CF and CH from the JANAF Tables, yields $\Delta H_f^\circ_{298} (C_2HF, g) = 30 \pm 15 \text{ kcal/mol}$.

Heat Capacity and Entropy

G. R. Hunt and M. K. Wilson, J. Chem. Phys. 24, 1301 (1961), and J. K. Brown and J. K. Tyler, Proc. Chem. Soc. (London) 1961, 13 (1961), have reported the infrared spectrum and have assigned the fundamental frequencies. The frequencies used in the present table are median values of the two sets and are generally within 5 cm^{-1} of each set.

The molecule has been shown to be linear by J. K. Tyler and J. Sheridan, Trans. Faraday Soc. 59, 2661 (1963), who reported the rotational constant B_0 .

The electronic ground state is assumed to be $^1\Sigma$ by analogy with C_2H_2 .

Values of α_i not available.

Heat of Formation

Taken from D. D. Wagman, J. E. Kilpatrick, K. S. Pitzer, and P. D. Rossini, J. Research Natl. Bureau Standards 55, 467 (1945).

Heat Capacity and Entropy

J. S. Gordon (private communication, February, 1961) has used the constants listed above to calculate C_p from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954). The constants are from E. E. Bell and H. H. Nielsen, J. Chem. Phys. 18, 1382 (1950) and H. C. Allen, E. D. Tidwell, and E. K. Plyler, J. Research Natl. Bureau Standards 57, 213 (1956). Heat capacities below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

Heat of Formation.

The heat of combustion of ethylene was measured by F. D. Rossini and J. W. Knowlton, *J. Res. Natl. Bur. Std.* **19**, 249 (1937). From the value, ΔH_f⁰ 298.15 = -337.28 ± 0.07 kcal. mole⁻¹ for the reaction C₂H₄(g) + 3 O₂(g) = 2 CO₂(g) + 2 H₂O(l), the heat of formation (ΔH_f⁰ 298.15) for C₂H₄(g) was derived to be 12.54 ± 0.07 kcal. mole⁻¹. The values of ΔH_f⁰ 298.15 for CO₂(g) and H₂O(l) used for calculation were obtained from F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine, and Irving Jaffe, "Selected Values of Chemical Thermodynamic Properties", Circular of the National Bureau of Standards 500, 1952.

Heat Capacity and Entropy.

The molecular structure, bond distances and angles were obtained from H. C. Allen, Jr. and E. K. Plyler, *J. Am. Chem. Soc.* **80**, 2673 (1958). The vibrational frequencies were taken from W. L. Smith and I. M. Mills, *J. Chem. Phys.* **40**, 2095 (1964). Eight of the twelve frequencies were reported by R. L. Arnett and B. L. Crawford, *J. Chem. Phys.* **19**, 118 (1950); B. L. Crawford, J. E. Lancaster and R. Inakeep, *J. Chem. Phys.* **21**, 676 (1953); B. P. Stoicheff, *J. Chem. Phys.* **21**, 755 (1953); T. Feldman, J. Romanko and H. L. Welsh, *Can. J. Phys.* **34**, 737 (1956); and H. C. Allen and E. K. Plyler, loc. cit. G. Herzberg, "Infrared and Raman Spectra", D. Van Nostrand Company, Inc., New York, 1945, also reported the vibrational frequencies for ethylene as 3019.3 (1), 1623.3 (1), 1342.4 (1), 825.0 (1), 3272.3 (1), 1050 (1), 949.2 (1), 943 (1), 3105.5 (1), 995 (1), 2989.5 (1) and 1443.5 (1) which are very close to the values adopted. The infrared and Raman spectra of ethylene before 1945 have been summarized by G. Herzberg, loc. cit. The molecular structure of ethylene was also determined by L. S. Bartell and R. A. Bonham, *J. Chem. Phys.* **27**, 1414 (1957). Their results, r_{C-H} = 1.085 Å, r_{C-C} = 1.334 Å and ∠H-C-H = 116° are in excellent agreement with the values adopted. The three principal moments of inertia are I_A = 0.5762 × 10⁻³⁹, I_B = 2.7999 × 10⁻³⁹ and I_C = 3.3761 × 10⁻³⁹ g.² cm.²

Heat of Formation.

The heat of combustion of ethylene oxide (g) was determined by A. S. Fell and G. Filcher, *Trans. Faraday Soc.*, 51, 71 (1955) and R. S. Crag and H. Hunt, *J. Phys. Chem.*, 46, 1162 (1942), as -312.15 ± 0.14 and -312.55 ± 0.20 kcal. mole⁻¹, respectively. The corresponding value of ΔH_f^o 298.15 (C₂H₄O, g) was evaluated to be -12.56 ± 0.15 and -12.19 ± 0.22 kcal. mole⁻¹. The former value is adopted.

Heat Capacity and Entropy.

The vibrational frequencies were taken from R. C. Lord and B. Nollin, *J. Chem. Phys.*, 24, 658 (1956). The infrared and Raman spectra of ethylene oxide have also been examined by J. W. Linnett, *J. Chem. Phys.*, 6, 692 (1938) and H. W. Thompson and M. T. Cave, *Trans. Faraday Soc.*, 47, 946 (1951). The vibrational frequencies assigned were slightly different from the ones reported by R. C. Lord and B. Nollin, loc. cit. As a result of analogies between ethylene oxide and ethylene imine, small changes of R. C. Lord and B. Nollin's assignment have been made by W. J. Potts, *Spectrochim. Acta*, 21, 511 (1965). The bond distances and angles were obtained from G. L. Cunningham, A. W. Boyd and W. D. Ginn, *J. Chem. Phys.*, 17, 211 (1949). The investigation of the structure of ethylene oxide by electron diffraction was reported by F. C. Ackermann and J. E. Mayer, *J. Chem. Phys.*, 21, 377 (1956) and M. Igarashi, *Bull. Chem. Soc. Japan*, 26, 330 (1953). The three principal moments of inertia are: I_A = 3.9052 X 10⁻³⁹, I_B = 3.2788 X 10⁻³⁹ and I_C = 5.9499 X 10⁻³⁹ g.² cm.²

The calculated heat capacities (307.2 - 371.2°K.) are in good agreement with the experimentally measured ones reported by G. B. Kistiakowsky and W. W. Rice, *J. Chem. Phys.*, 9, 618 (1940).

Heat of Formation

A. J. Merer and D. N. Travis, Can. J. Phys. **44**, 353 (1966), state that the observed bond length in CNC(g) indicates double-bonded CN links. The value of the C = N dissociation energy is derived as 147 kcal from the heat of combustion of n-butyl-isobutylidene amine determined by G. E. Coates and L. E. Sutton, J. Chem. Soc. 1187, (1948). However, due to possible extra binding energy from the unpaired electron, we assume here a slightly higher value of 160 kcal. This yields a $\Delta H_f^\circ(\text{CNC}, g) = 133 \text{ kcal/mol}$. It is also possible to calculate another value by assuming that the ratio of the heat of atomization (ΔH_a) of Si₂N to that of C₂N(g) is equal to the ratio of the dissociation energies of SiN(g) and CN(g); by this method $\Delta H_f^\circ(\text{CNC}, g) = 144 \text{ kcal/mol}$.

Heat Capacity and Entropy

Merer and Travis, loc. cit., have observed the ultraviolet absorption spectrum of the CNC radical. They have assigned the configuration, bond distance, and the electronic levels. In addition, they have derived w_p , the remaining frequencies are estimated by comparison with the w_p of Si₂N(g), which has been assigned by W. Weltner and D. J. McLeod, J. Chem. Phys. **40**, 1305 (1964), and J. Chem. Phys. **45**, 3096 (1966).

Rotational constant B₀ = 0.15752 ± 0.00015 cm.⁻¹ CN distance = 1.157 Å CC distance = 1.380 Å σ = 2

Moment of Inertia = 1.776 (g) × 10⁻³⁸ g. cm.²

Heat of Formation

J. W. Knowlton and E. J. Frosen, J. Research Natl. Bur. Standards 45, 489 (1951), report ΔH_f° 298.15 = -281.94 ± 0.43 kcal. for the reaction C₂N₂(g) + 2 O₂(g) → 2 CO₂(g) + N₂(g). When corrected for a change in the atomic weight of carbon, this becomes ΔH_f° 298.15 = -261.95 ± 0.43 kcal., whence ΔH_f° 298.15 for C₂N₂(g) is found to be 73.87 ± 0.43 kcal. mole⁻¹.

Heat Capacity and Entropy

A Langseth and C. K. Møller, Acta Chem. Scand. 4, 725 (1950), determined the vibrational frequencies by Raman spectroscopy. C. K. Møller and B. P. Stoicheff, Can. J. Phys. 32, 625 (1954), determined B₀ by Raman spectroscopy and calculated the bond lengths listed above. These agree with lengths found from electron-diffraction measurements by Langseth and Møller, loc. cit., (CN distance = 1.15 Å, CC distance = 1.38 Å) and L. Pauling, H. D. Springall, and K. J. Palmer, J. Am. Chem. Soc. 61, 927 (1939) (CN distance = 1.15 ± 0.02 Å, CC distance = 1.37 ± 0.02 Å). From measurements reported by R. A. Ruehrwein and W. F. Glaue, J. Am. Chem. Soc. 61, 2940 (1939), S_{298.15} is calculated by the third law to be 57.63 cal. deg.⁻¹ mole⁻¹, in satisfactory agreement with the value calculated here.

Bond Angle: C-Na-C = [105]° Na-C-Na = [75]° N-C-Na = [142.5]°

Product of the Moments of Inertia: I_AI_BI_C = [4.48269 X 10⁻¹¹³] g.³ cm.⁶

Heat of Formation.

The mass spectra of vapors from samples of NaCN have been observed by R. F. Porter, J. Chem. Phys. **35**, 318 (1961), at temperatures around 1000°K. The results indicate that the compound evaporates as NaCN(g) and Na₂(CN)₂(g). A comparison of relative ion currents produced by electron bombardment of NaCN vapors effusing from single - and double-oven-type Knudsen cells, yielded information on the partial pressures of monomer and dimer. Based on the partial pressures for NaCN(g) and (NaCN)₂(g) reported at temperatures, 803-1049°K., the vapor pressures of (NaCN)₂(g) over NaCN(l), 1078.2-1026.2°K., were calculated from the total vapor pressure measurements reported by C. K. Ingold, J. Chem. Soc. 123, 885 (1923). By the second and third law methods, the values of ΔH_f⁰ 298.15 (1 → dimer) were evaluated to be 38.89 and 38.21 kcal. mole⁻¹, respectively. Using the third law value, the heat of formation for (NaCN)₂(g) was evaluated.

Heat Capacity and Entropy.

The molecular structure, bond distances and C-Na-C bond angle were estimated by R. F. Porter, loc. cit. The vibrational frequencies were estimated by comparison with those for NaCl(g). The last six frequencies were the bending and asymmetric stretching frequencies for NaCN(g). The three principal moments of inertia are: I_A = 1.3570 X 10⁻³⁸, I_B = 5.1030 X 10⁻³⁸ and I_C = 6.4660 X 10⁻³⁸ g. cm.²

Bond Angle: C-C-O = [180]°

Rotational Constant: B₀ = [0.408475] cm⁻¹

σ = 1

Heat of Formation

The adopted heat of formation, ΔH_f⁰ = 68.5 kcal/mol, was calculated from the heat of reaction ΔH_f⁰ = 65.5 kcal/mol for C₂O(g) + CO(g) = C₂O₂(g) using all JANAF functions (dated Sept. 30, 1965). The value of ΔH_f⁰ was obtained from the third law calculation of the equilibrium constant (K_p = 3.3 x 10⁻⁶ atm at 1060°K) which was determined in the studies of decomposition rate of C₂O₂(g) by H. B. Palmer and W. D. Cross, Carbon 3, 475 (1966).

M. E. Jacox, D. E. Milligan, N. G. Moll, and W. E. Thompson, J. Chem. Phys. 43, 3745 (1965), have observed the photo-dissociation of C₂O near 5000 Å, which corresponds to a minimum of 57 kcal/mol for C₂O(g) → C(g) + CO(g). This yields ΔH_f⁰(C₂O, g) ≤ 87 kcal/mol, which was not adopted because the irradiation was not monochromatic and thus possibly contained all wavelengths below 5000 Å.

Heat Capacity and Entropy

Jacox et al., loc. cit., have observed three vibrational fundamentals in the infrared spectrum by matrix isolation, and suggested a linear structure with Σ ground state for the CCO radical (g). They also estimated the bond distances C-C = 1.160 Å and C-O = 1.279 Å based on the structural analogy between the carbon suboxide and the CCO radical. The principal moment of inertia is 8.825 x 10⁻³⁵ g cm². K. D. Bayes, J. Am. Chem. Soc. 85, 1730 (1963), has predicted that the Λ and Σ states lie respectively 0.5 and 0.8 eV above the ground state. These two electronic states have been included in the tabulation.

$$\Delta H_f^\circ = 145.6 \pm 7 \text{ kcal/mol}$$

$$\Delta H_f^\circ_{298.15} = 147 \pm 7 \text{ kcal/mol}$$

Heat of Formation.

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor equilibria over the systems SiC-graphite¹, SiC-silicon², and boron-carbon-silicon³. Third law analysis of the partial pressures of C₂Si and Si lead to the concordant values 146.7, 149.0 and 146.0 kcal/mol. Although the drifts all suggest that the entropy of C₂Si may be about 3.5 eu less than tabulated, this is of doubtful significance because the uncertainty bands are so large. The low condensation coefficient suggested by Drowart⁴ may also be involved. Rates of free evaporation reported by Voronin⁵ lead to apparent pressures which are smaller by a factor of 1/30, thus confirming the existence of a low evaporation coefficient. The adopted value of $\Delta H_f^\circ_{298} = 147 \pm 7$ kcal/mol includes allowance for the unlikely possibility that the entropy may be in error by up to 3.5 eu.

Source	Method	Reaction	Range, T°K	No. of Points	$\Delta H_f^\circ_{298}$ (kcal/mol)	Drift (eu)

						146.0

Heat Capacity and Entropy.

The known molecular constants are from the assignments of Welter and McLeod⁵. These authors observed the infrared spectrum, emission spectrum and visible absorption spectrum of C₂Si in matrix isolation. The matrix data allowed more certain assignment of the A-X band system of the gas as observed by Klemm⁶ and McKellar⁷. Welter concluded that this system probably involves transitions between a ¹Σ⁺ ground state and a ¹Π excited state. The two stretching frequencies were observed in the matrix infrared spectrum, whereas the bending mode, 300 cm⁻¹, was derived solely from the analysis of the A-X band system. The analysis presumed a linear unsymmetrical structure for the molecule.

A ³Π excited state is assumed to lie 7000 cm⁻¹ below the ¹Π state, which presumably arises from the same molecular orbital configuration. The effect of the estimated level is to increase the entropy by about 0.2 and 1.8 eu at 3000 and 6000°K. Bond distances are estimated by comparison with those in Si₂, C₂ and C₃. The moment of inertia is 13.91 x 10⁻⁵⁹ g cm².

Dec. 31, 1960, Dec. 31, 1969

The contribution of the doubly degenerate bending frequency was approximated by direct summation of the following levels (cm⁻¹): 0, 63.5, 132.7, 207.4, 286.5, 370.5, 458.2, and 650 x n where n = 1 to 76. The contribution to each function due to these levels was doubled to account for the degeneracy.

Bond Distance: C-C = 1.277 Å

Bond Angle: C-C-C = 180°

Rotational Constant: B₀ = 0.4305 cm⁻¹

σ = 2

Heat of Formation

Drowart et al. (1) have measured mass spectrometrically the ion intensity ratio C₃⁺/C⁺ as a function of temperature from 1800 to 2700°K. We derive from a 2nd law analysis of their data ΔH₂₇₀₀⁰ = 185.2 ± 3.3 kcal, and S₂₀₀₀⁰ = 74.9 ± 2.8 eu by calculation of the absolute pressure from the vapor pressure of monatomic carbon and a relative ionization cross-section ratio of 2.3. The entropy uncertainty includes 1.3 eu for uncertainty in the absolute pressure. Several earlier mass-spectrometric determinations (2, 3, 4) are in reasonable agreement. The absolute magnitude of the pressure is also confirmed by the work of Thorm and Winslow (5) who measured the total pressure of all species over graphite as 1.2 to 4.8 x 10⁻⁷ atm. at 2400°K.

Subtracting the JANAF values for C and C₂ we obtain C₃ = 5.4 x 10⁻⁸ to 2.2 x 10⁻⁷ atm., which compares with Drowart's value of 3.3 x 10⁻⁸ to 1.3 x 10⁻⁷ atm. The 2nd law heat of formation is reported (3) to be ΔH₂₄₀₀⁰ = 184.4 but the range is only 80°K. It does, however, confirm the magnitude of the mass-spectrometric values for both heat and entropy. We have adopted a heat of formation within the uncertainty limits of Drowart's measurements which with the adopted functions yields pressures in the 2000-3000°K range consistent with the measurements. We were not able to generate functions which agree exactly with the 2nd law entropies, since even direct summation over only the observed levels of the bending frequency gives an entropy which is already too large.

Heat Capacity and Entropy

The stretching frequencies are from Merer (6), Weltner et al. (7) and Weltner and McLeod (8). The bending frequency and its harmonics are from Gausset et al. (9) and Merer (6). The rotational constant and bond distance are from Gausset et al. (9).

As indicated briefly above, the calculated entropy of C₃ gas is higher than the experimental value even when a summation is performed only over the observed first six levels of the bending frequency. Treatment of the vibration as a harmonic oscillator or as an anharmonic oscillator gives values considerably higher. Straus and Thiele (10) have also calculated functions based on a quartic potential function which still yields values several units higher than the experiments. In order to reduce the entropy to the approximate range of the measurements we have made the assumption that the potential function is of an unusual form above the sixth vibrational level. We assume that the large amplitude of the bending vibration causes a drastic change in the function, possibly due to the increasing repulsion between end carbons, as the amplitude increases. Thus, we assume a very steeply rising potential above the sixth vibrational level. We have chosen to represent this part of the potential by a harmonic oscillator of 650 cm⁻¹. The choice of 650 cm⁻¹ is arbitrary, but is not unreasonable for a bending vibration, and yields functions which approximate the experimental data.

In order to explain the observed spectrum of C₃O₂, a molecule with a bending frequency of 63 cm⁻¹, Smith and Barrett (11) have proposed that potential maxima occur in the bending potential away from linearity. Thus, the adoption of an unusual potential function for C₃ bending may be justifiable. We do not claim that our functions are necessarily correct but only that they include all known facts and satisfy the experimental equilibrium observations. Further investigation of the carbon vapor pressure and of the higher vibrational levels of C₃ is desirable.

Dec. 31, 1960; June 30, 1963; Sept. 30, 1965

$\Delta H_f^0 = -50.35 \pm 1.6$ kcal. mole⁻¹
 ΔH_f^0 298.15 = -51.55 \pm 1.6 kcal. mole⁻¹
 ΔH_m^0 = Unknown

$S_{298.15} = 21.26 \pm 0.3$ cal. deg.⁻¹ mole⁻¹
 $T_m = [2500]^\circ K.$

Heat of Formation.

The ΔH_f^0 298.15 = -51.55 \pm 1.6 kcal. mole⁻¹ is the average value of ΔH_f^0 298.15 = -49.7 \pm 1.2 kcal. mole⁻¹ by R. C. King and G. T. Armstrong, National Bureau of Standards Report No. 8504 (1964) and that of ΔH_f^0 298.15 = -53.4 \pm 2.0 kcal. mole⁻¹ by A. D. Meh, United States Bureau of Mines, Report No. 6415 (1964). Both measured the heat of reaction $Al_4C_3(c) + 6O_2(g) \rightarrow 2Al_2O_3(c, w) + 3CO_2(g)$ and used their ΔH_f^0 298.15 and the ΔH_f^0 298.15 of $Al_2O_3(c)$ and $CO_2(g)$ to calculate the ΔH_f^0 298.15 of $Al_4C_3(c)$. The ΔH_f^0 298.15 measured by King and Armstrong was -1033.3 \pm 1.1 kcal. mole⁻¹, the ΔH_f^0 298.15 measured by Meh was -1029.6 \pm 1.9 kcal. mole.

Heat Capacity and Entropy.

The low temperature heat capacities, 18-390°K., were measured by W. G. Saba and G. T. Furukawa, National Bureau of Standards Report 7587, July 1, 1962. The high temperature heat capacities, 275-1173°K., were measured by A. C. Victor, W. R. Thurber, and T. B. Douglas, National Bureau of Standards Report 7437, January 1, 1962. These two sets of heat capacity data were joined smoothly and extrapolated to 2000°K. by W. G. Saba and G. T. Furukawa, loc. cit. The values of C_p above 2000°K. were estimated by extrapolation graphically. $S_{298.15}^0$ was reported by W. G. Saba and G. T. Furukawa, loc. cit., using $S_{298.15}^0(\text{extrap.}) = 0.013$ cal. deg.⁻¹ mole⁻¹.

Melting Temperature.

T_m was estimated by O. Ruff and E. Jellinek, Z. anorg. u. allgem. Chem. 37, 312 (1916).

Dimagnesium Tricarbide (Mg_2C_3)

Bond Distances: C-C = 1.28 Å C-O = 1.16 Å

Bond Angles: C-C-C = 180° O-C-C = 180°

Rotational Constant: B₀ = 0.073206 cm⁻¹

σ = 2

Heat of Formation

Kybett et al. (1) have determined the heat of combustion of the liquid form under its own pressure using the sample from the heat capacity determinations (2).

The average of four determinations gave $\Delta H^{\circ}_{298}(l) = -28.03 \pm 0.24$ kcal/mol; the authors report -29.03 due to an arithmetic error. The sample was 99.98 mole percent pure. McDougall et al. (2) measured $\Delta H^{\circ}_{298}(g) = 6.421 \pm 0.012$ kcal/mol from which we calculate $\Delta H^{\circ}_{298}(g) = 5.65 \pm 0.2$ kcal/mol. Thus the heat of formation of the gas is found to be -22.38 ± 0.44 kcal/mol.

Heat Capacity and Entropy

There has been considerable controversy as to the configuration of this molecule and the assignment of its vibrational frequencies. However, the evidence seems fairly conclusive for the linearity of the molecule from the work of Lafferty et al. (3) and Miller et al. (4). The rotational constant adopted here is that found by Lafferty et al. (3) and the vibrational frequencies are those reported by Miller et al. (4), except for ν_7 which is taken from Miller et al. (5) and Borgers (7). The low frequency ν_u mode is confirmed by the work of McDougall et al. (2), who measured the low temperature entropy of C₃O₂(c) and (4) and also the heat of vaporization. From a comparison of the entropy calculated statistically and that measured, they conclude $\nu_7 = 63.2$ cm⁻¹. The values adopted are confirmed by third law analysis of the vapor pressure data of McDougall et al. (5) which indicate a heat of vaporization in fair agreement with their calorimetric value. The drift in the third law analysis indicates that the entropy of the solid is too low or that of the gas is too high by 1 eu. Alternatively as systematic error in the pressure measurements could have caused this deviation.

The bond distances are taken from the electron diffraction experiments of Livingston et al. (6) and are in good accord with the adopted rotational constant.

Heat of Formation

O. T. Armstrong and S. Marantz, J. Phys. Chem. 64, 1776 (1960), measured the heat of combustion of the liquid for which they obtain a ΔH_f° 298.15 of 120.6 kcal. mole⁻¹ using 94.05 kcal. mole⁻¹ for ΔH_f° 298.15 of CO₂(g). They calculate the ΔH_f° 298.15 of C₄N₂(g) with a ΔH_{vap} taken from A. J. Saggio, J. Org. Chem. 22, 1171 (1957).

Heat Capacities and Entropies

Bond lengths determined by P. A. Miller and R. B. Hamman Jr., J. Chem. Phys. 21, 110 (1953) from X-ray diffraction measurements on the solid. The vibrational frequencies were observed in the infra red and Raman by F. A. Miller, R. B. Hamman Jr., and L. R. Cousins, J. Chem. Phys. 23, 2127 (1955).

Heat of Formation

The heat of formation is obtained from the mass-spectrometric results of Drowart et al. (1) who obtained ΔHf_{298.15}⁰ = 230 ± 5 kcal/mol. This was obtained from a 2nd law analysis of the ion intensity ratio C₅⁺/C⁺ over a temperature range of 2200-2700°K. The absolute pressure, obtained from a knowledge of the monatomic carbon vapor pressure and an estimated ionization cross-section ratio of 6.3, yields a 2nd law entropy at 2400°K of 103.7 ± 2 eu. The uncertainty in the ionization cross-section ratio is probably no more than a factor of two which gives an overall entropy uncertainty of ±3.5 eu. The heats of formation at temperatures other than 2400°K depend on the functions adopted, for a discussion of these see below.

Heat Capacity and Entropy

The molecular properties of C₅ are all estimated. We have chosen a set of functions which is consistent with the mass-spectrometric observations of Drowart et al. (1). The thermodynamic functions of C₅ were first estimated by Pitzer and Clementi (2) but the basis for this estimate has completely changed. Originally they were calculated by analogy with C₃, C₃O₂ and CO₂, but the discovery of very low bending frequencies in C₃ and C₃O₂ complicated the picture by raising the calculated entropies significantly. Sandborn (3) has correlated the bending force constants in several related triatomics and has estimated the vibrational frequencies in C₄ and C₅. These vibrational frequencies yield high entropies outside the limits of the second law determination. Since these frequencies are estimates, based on a basically triatomic correlation we have chosen to adopt three doubly degenerate bending frequencies of 550 cm⁻¹ in place of the 130 cm⁻¹, 330 cm⁻¹ and 520 cm⁻¹ frequencies estimated by Sandborn. The basis for this change is to make the functions conform to the only available measured data. Use of the present tables will yield values for the vapor pressure of C₄ in excellent agreement with the measurements in the 2000-3000°K range. Outside this range they provide only a general indication of the variation since they may not correspond to the real situation.

The stretching frequencies are from Sandborn (3) and the bond length is estimated equal to that in C₃.

Heat Capacity and Entropy

The low temperature heat capacity data of Griffel et al. (1), 1.8° to 4.2°K, Roberts (2), 1.5° to 20°K, and Clusius and Vaughan (3), 10° to 200°K, were fit with polynomial expressions. Up to 20°K the three sets fit the adopted curve within ± 6 with a maximum deviation of 14%. This is considered excellent agreement since the heat capacity is only 0.35 gibbs/mol at 20°K. From 20° to 200°K the data of Clusius were within $\pm 1\%$ of the adopted polynomial. The data of Gunther (4), 22° to 62°K, generally deviated from the adopted curve by 10%. The polynomial fit of the data of Clusius was arranged to be linear in temperature at high temperatures and was extrapolated to 298°K. The data of Eastman et al. (5), 67° to 293°K, were consistently high by 5.8 to 9% over the whole range. The extrapolation of the heat capacity to 6.28 gibbs/mol at 298°K is further justified by comparison with the heat capacity of magnesium, which is almost identical to that of calcium over the whole range, if its temperature scale is multiplied by 0.75.

The heat capacity between 298° and 721°K was obtained by forcing a polynomial of the type $H = aT^2 + bT + c + d/T$ through 298° with a slope of 6.28 and also through a value of $H_{721} = 2736$ cal, and making a good fit of the adopted low temperature enthalpies. The choice of $H_{721} = 2736$ cal was made, since Zalesinski and Zulinsky (6), Jauch (7), and Eastman et al. (8) were in essential agreement in the beta-phase at this temperature. The enthalpy of transition was subtracted to give the adopted value. The individual measurements of Jauch (7) were not available, but the value at 720°K could be read from a small plot with reasonable accuracy; Eastman et al. (8) gave only an equation for their data. There is no question that reliable measurements of the heat capacity and enthalpy are needed in the range 200° to 700°K.

Transition Data

The temperature of transition was that reported by Peterson and Fattore (9) and confirmed by Chiotti et al. (10). Earlier reports on impure specimens ranged from 718° to 737°K and were not considered. The heat of transition was measured by Chiotti et al. (10) using an adiabatic high temperature calorimeter, and is in agreement with that reported by Kubaschewski (11) of 0.24 ± 0.04 kcal from enthalpy data.

Sublimation Data

See Ca(g) for details.

CALCIUM, BETA (Ca)

(CRYSTAL)

GFV = 40.08

 ΔH°_0 = unknown $\Delta H^\circ_{298.15} = 10.15$ gibbs/mol $T_t = 721 \pm 2^\circ\text{K}$ $T_m = 1112 \pm 2^\circ\text{K}$ $\Delta H^\circ_t = 0.220 \pm 0.05$ kcal/mol $\Delta H^\circ_m = 2.04 \pm 0.10$ kcal/mol

Heat of Formation

Obtained from that of α -Ca by adding ΔH°_t and the difference in $H^\circ_{721} - H^\circ_{298}$ for α - and β -Ca.

Heat Capacity and Entropy

The enthalpy at 721°K was fixed as described on the α -Ca table. The data of Jauch (2), and Zalesinski and Zulinski (2), and Eastman et al. (3) were then fitted by an equation of the form $H = a + bT + cT^2$ where $a = -1315$, $b = 4.014$ and $c = 0.00285$. The values of Jauch, read from a small graph, fit within 1% generally and within 2% maximum deviation; those of Zalesinski and Zulinski fit within 0.7% with the exception of the highest point which differed by 1.8%. The data of Eastman et al. vary from 3.6% high to 0.4% low. The entropy was obtained in a manner analogous to the heat of formation.

Transition Data

See the α -Ca table for details.

Melting Data

The melting point is that reported by Peterson and Fattore (4) and confirmed by Chioffi et al. (5). Earlier reports on less pure specimens ranged from 1083° to 1122°K . The heat of melting was measured by Chioffi et al. (5) using an adiabatic high temperature calorimeter, and is in agreement with that reported by Kubaschewski (6) of 2.07 ± 0.1 kcal/mol from enthalpy data.

CALCIUM (Ca)

(LIQUID)

GFW = 40.08

 $S^\circ_{298.15} = 12.105$ gibbs/mol $\Delta H^\circ_{298.15} = 2.606 \pm 0.1$ kcal/mol $\Delta H_m^\circ = 2.04 \pm 0.10$ kcal/mol $T_m = 1112 \pm 2^\circ\text{K}$ $\Delta H_v^\circ = 36.9668$ kcal/mol $T_b = 1767.4 \pm 15^\circ\text{K}$

Heat of Formation

Obtained from that of β -Ca by adding ΔH_m° and the difference between $H_{1112} - H_{298}$ for β -Ca and liquid.

Heat Capacity and Entropy

The heat capacity was derived as constant from the enthalpy values of R. Jauch, Diplomarbeit, Techn. Hochschule Stuttgart, 1946, quoted by O. Kubaschewski, Z. Elektrochem. 51, 275 (1950). The entropy was obtained in a manner analogous to the heat of formation.

Melting Data

See the β -Ca table for details.

Vaporization Data

T_b is calculated from the free energy crossovers of the Ca(l) and Ca(g) tables, and ΔH_v° is the difference between $\Delta H^\circ_{1767.4}$ for liquid and gas.

Ground State Configuration $1s^2$
 $S^{\circ}_{298.15} = 36.992 \pm 0.005$ gibbs/mol
 $\Delta H^{\circ}_0 = 42.74 \pm 0.3$ kcal/mol
 $\Delta H^{\circ}_{298.15} = 42.85 \pm 0.30$ kcal/mol

Electronic Levels and Quantum Weights
 $\epsilon_i, \text{ cm}^{-1}$ g_i $\epsilon_i, \text{ cm}^{-1}$ g_i

Heat of Formation
The vapor pressure over solid and liquid calcium has been reported by several authors. The results of our analysis of their data are presented in the following table. By using free energy functions based on the α crystal at 298°K all the data yield $\Delta H^{\circ}_{298.15}$ (Ca, c) which is $\Delta H^{\circ}_{298.15}$ (Ca, g).

Heat Capacity and Entropy
The electronic levels and quantum weights were obtained from Moore (13), and were cut off at 45000 cm^{-1} , which is approximately the ionization limit minus KT for the maximum temperature. All of the unobserved terms in the spectrum are estimated to occur between 47000 cm^{-1} and the ionization limit.

Heat of Formation

N. D. Potter (1) investigated mass spectrometrically the gaseous equilibria among Ca, CaCl, and CaCl₂. Ion intensities were measured 2.5 eV above the ionization threshold. Using the equilibrium constants $K = I(\text{Ca})I(\text{CaCl}_2)/I(\text{CaCl})^2$ which we calculated from the reported ion intensities for the reaction $\text{Ca(g)} + \text{CaCl}_2(\text{g}) \rightleftharpoons 2\text{CaCl(g)}$ in the temperature range 1252°-1557°K, we obtain $\Delta H^{\circ}_{f,298} = 15.81$ kcal/mol by the third law method. The third law drift is -2.8 ± 3.5 eu. The heat of formation is derived as $\Delta H^{\circ}_{f,298}(\text{CaCl, g}) = -27.0$ kcal/mol.

K. F. Zmbov (2) determined by mass spectrometry the heat of the above reaction as 24.4 ± 1.3 kcal/mol with a drift of 12.5 ± 9.4 eu. This yields the heat of formation, $\Delta H^{\circ}_{f,298}(\text{CaCl, g}) = -22.7$ kcal/mol.

D. L. Hildenbrand (2) also determined the equilibrium constants for the reaction (a) $\text{Ca(g)} + \text{CaCl}_2(\text{g}) \rightleftharpoons 2\text{CaCl(g)}$ and the reaction (b) $\text{Ca(g)} + \text{AlCl}_3(\text{g}) \rightleftharpoons \text{CaCl(g)} + \text{Al(g)}$ by mass spectrometry in the temperature range 1219-1353°K. Third law analysis of the reported equilibrium constants gives $\Delta H^{\circ}_{f,298} = 21.08$ kcal/mol and drift = -1.4 ± 1.8 eu for reaction (a); $\Delta H^{\circ}_{f,298} = 24.20$ kcal/mol and drift = 0.5 ± 1.3 eu for reaction (b). From third law $\Delta H^{\circ}_{f,298}$ of (a) and (b), we derived $\Delta H^{\circ}_{f,298}(\text{CaCl, g})$ as -24.4 and -23.3 kcal/mol, respectively, using all JANAF functions. Hildenbrand has also derived a corrected $D_0(\text{Ca-Cl}) = 95.0$ kcal/mol from a linear Birge-Sponer extrapolation of the ground state vibrational levels with correction for its ionicity. This corrected $D_0(\text{Ca-Cl})$ yields the heat of formation, $\Delta H^{\circ}_{f,298}(\text{CaCl, g}) = -23.9$ kcal/mol.

Ryabova and Gurvich (3) reported $D_0(\text{Ca-Cl}) = 102 \pm 6$ kcal/mol from flame spectra studies. This leads to $\Delta H^{\circ}_{f,298}(\text{CaCl, g}) = -30.8$ kcal/mol.

D. L. Hildenbrand (5) determined the dissociation energy of $\text{CaCl}_2(\text{g})$ by electron impact as $D_0(\text{CaCl-Cl}) = 5.04 \pm 0.02$ eV which, combined with JANAF $\Delta H^{\circ}_{f,298}$ of $\text{CaCl}_2(\text{g})$ and Cl(g) gives $\Delta H^{\circ}_{f,298}(\text{CaCl, g}) = -23.1$ kcal/mol.

A weighted average, $\Delta H^{\circ}_{f,298}(\text{CaCl, g}) = -25 \pm 3$ kcal/mol, is adopted in the tabulation.

Heat Capacity and Entropy

The vibrational constants (ω_e and $\omega_e x_e$), electronic levels and ground state configuration were taken from Herzberg (4). Morgan and Barrow (5) made rotational analysis of the $C^2\Pi-X^2\Sigma$ system and reported $B_e = 0.1516$ cm⁻¹ and $r_e = 2.439$ Å for the ground state. The value of q_e is calculated from the Morse potential function. The F and G states were reported by Schutte (6).

Heat of Formation

V. B. Parker (1) has selected the standard heat of formation as -190.2 kcal/mol which is adopted in the tabulation. The heat of formation was derived from two independent paths. The first path involves $\Delta H_{298}^\circ(\text{Ca}^{++}, \infty \text{H}_2\text{O}) = -129.74$ kcal/mol (1), $\Delta H_{298}^\circ(\text{Cl}^-, \infty \text{H}_2\text{O}) = -39.952$ kcal/mol (2) and the heat of solution of $\text{CaCl}_2(\text{c})$ in water (3, 4, 5, 6, 7). The second path involves the heats of reaction of $\text{Ca}(\text{c})$, $\text{CaO}(\text{c})$ and $\text{CaCl}_2(\text{c})$ in aqueous HCl solution (4, 5-20).

Heat Capacity and Entropy

Kelley and Moore (21) measured the low temperature heat capacities in the temperature range from 52.6° to 295.1°K and made an extrapolation to 0°K which yielded an entropy of 4.59 ± 0.4 eu at 50.12°K. We have adopted the measured heat capacities, but made our own extrapolation to 0°K by comparison with the measured heat capacities of $\text{BaCl}_2(\text{c})$ (22) and $\text{SrCl}_2(\text{c})$ (23) from 6° to 50°K. The extrapolation gives $S_{50}^\circ = 2.45 \pm 1$ eu, which is used in the table. Moore (24) measured high temperature enthalpy data from 403.7° to 1667°K by drop calorimetry. The low temperature heat capacities and high temperature enthalpy data are smoothly joined at 298°K. The deviations of the observed enthalpies from the adopted values are about 21 near 400-500°K and only a few tenths percent at higher temperatures. Dworkin and Bredig (25) determined drop-calorimetrically $H_{1045}^\circ - H_{298}^\circ = 14.3$ kcal/mol, which is in very good agreement with the adopted value of 14.2 kcal/mol.

Melting Data

The adopted melting point 1045°K was determined by T. V. Tokareva (26). Dworkin and Bredig determined the heat of fusion $\Delta H_{1045}^\circ = 6.78 \pm 0.1$ kcal/mol by drop calorimetry. Chiotti, Gartner, Stevens and Saito (27) also measured the heat of fusion $\Delta H_{1055}^\circ = 6.79 \pm 0.2$ kcal/mol in an adiabatic calorimeter. The adopted heat of fusion, 6.822 kcal/mol, is calculated from the difference between the observed relative enthalpy of the liquid and the adopted value for the crystal at the melting point.

Sublimation Data

The heat of sublimation is calculated from the heats of formation of $\text{CaCl}_2(\text{c})$ and $\text{CaCl}_2(\text{g})$.

$S_{298.15}^{\circ} = 29.608 \pm 1.2$ gibbs/mol
 $\Delta H_f^{\circ} = -185.013 \pm 0.5$ kcal/mol
 $\Delta H_m^{\circ} = 6.822 \pm 0.2$ kcal/mol
 $\Delta H_v^{\circ} = 56.2$ kcal/mol

$T_m = 1045^{\circ}\text{K}$
 $T_b = 2208.6^{\circ}\text{K}$

Heat of Formation
The heat of formation is calculated from that of the crystal by adding the heat of melting and the difference between H_{1045}° and H_{298}° for the crystal and the liquid.

Heat Capacity and Entropy
The constant heat capacity above the assumed glass transition at 700°K is derived from high temperature enthalpy data in a drop calorimeter from the melting point up to 1667°K by G. E. Moore, J. Amer. Chem. Soc. 65, 1700 (1943). Below the glass transition point, the heat capacity is assumed to be the same as that of the crystal. A. S. Dworin and M. A. Bredig, J. Phys. Chem. 67, 697 (1963), reported $C_p(l) = 23.6$ gibbs/mol from enthalpy measurements in a short temperature range by drop calorimetry.

The entropy $S_{298.15}^{\circ} = 29.608$ gibbs/mol is calculated in a manner analogous to that of the heat of formation.

Melting Data
See the crystal table for details.

Vaporization Data

The boiling point is calculated as the temperature at which $\Delta G = 0$ for $\text{CaCl}_2(l) + \text{CaCl}_2(g)$. The heat of vaporization is the difference in ΔH_f° between liquid and gas.

Bond Angle: Cl-Ca-Cl = 180°
Rotational Constant: $B_0 = 0.0377 \text{ cm}^{-1}$

Heat of Formation

Second and third law analyses of vapor pressure data are given below. The selected third law heat of vaporization is taken from Novikov's measurement (1) as $\Delta H_{298}^\circ = 72.30$ kcal/mol which is combined with ΔH_{298}° of the liquid to give $\Delta H_{298}^\circ(\text{CaCl}_2, g) = 112.7 \pm 1$ kcal/mol.

Third law analyses indicate zero drift for Novkov's data, positive and negative drifts for Hildenbrand's (2) and Bautista's (3) data, respectively. Their heats are in agreement within 1 kcal. Wartenberg (4) reported there was no boiling at 1819°K at 12 mm Hg pressure, and his value ($\Delta H_{298}^\circ = 71.1 \pm 0.7$ kcal/mol) serves as a guide for the minimum heat of vaporization.

Value in parentheses is the heat of sublimation.

Heat Capacity and Entropy

The linear structure and vibrational frequencies were determined by D. White and co-workers (6) in the matrix-infrared-spectrometric studies. The linear structure is consistent within experimental error with the electric-quadrupole-deflection studies (7), and electron-diffraction data (8). Hayes (9) has qualitatively rationalized the linear structure through molecular orbital theory.

The bond length was measured by Akishin and Spiridonov (8). The moment of inertia is $74.174 \times 10^{-39} \text{ g cm}^2$.

Calcium Difluoride (CaF₂)

(Crystal)

GFW = 78.0768

 $\Delta H_f^\circ = -292.3 \pm 1.5$ kcal/molCaF₂ $S_{298.15}^\circ = 16.39 \pm 0.08$ gibbs/mol $\Delta H_f^\circ = -293.0 \pm 1.5$ kcal/mol $T_m = 1424 \pm 20^\circ\text{K}$ (g-p) $\Delta H_f^\circ = 1.14 \pm 0.1$ kcal/mol $\Delta H_m^\circ = 7.10 \pm 0.1$ kcal/mol $\Delta H_{298.15}^\circ = 105.5 \pm 0.8$ kcal/mol

Heat of Formation

Torgeson and Sahama (1) measured the heat of solution of CaO in aqueous 20.1% HF as -54.96 ± 0.02 kcal/mol. Using ΔH_f° (CaO, c) = -151.79 kcal/mol (2), ΔH_f° (H₂O, l) = -68.317 kcal/mol (3) and ΔH_f° (HF, aq) = -76.60 kcal/mol (4), we obtain ΔH_f° (CaF₂, c) = -293.6 ± 0.6 kcal/mol.

Shvelyshev and Edeleva (5) report the solubility product of CaF₂ as $2.7 \pm 0.27 \times 10^{-11}$ in dilute HCl, which yields $\Delta G_{298}^\circ = 14.42$ kcal/mol for the reaction $\text{CaF}_2(\text{c}) + \text{Ca}^{2+}(\text{aq}) + 2\text{F}^-(\text{aq})$. Using ΔG_f° (Ca²⁺, aq) = -132.30 kcal/mol (2) and ΔG_f° (F⁻, aq) = -66.95 kcal/mol (4) we obtain ΔG_f° (CaF₂, c) = -280.84 ± 0.6 kcal/mol, which using the adopted functions yields ΔH_f° (CaF₂, c) = -293.1 ± 0.6 kcal/mol.

Vechev and Vechev (17) have measured the ent of a high temperature solid state cell and report $\Delta G_{1200}^\circ = -17.6 \pm 0.2$ kcal/mol for the reaction $\text{CaO}(\text{c}) + \text{MgF}_2(\text{c}) + \text{CaF}_2(\text{c}) + \text{MgO}(\text{c})$. This reduces to $\Delta H_{298}^\circ = -17.6$ kcal/mol which, using JANAF values for MgO and MgF₂ and CaO from reference 2, yields ΔH_f° (CaF₂, c) = -294.4 ± 1.3 kcal/mol.

Kohlrausch (18) reported the solubility of CaF₂ and fluorapatite, which yield solubility products of 3.6×10^{-11} and 2.8×10^{-11} . From these we obtain, as above, ΔH_f° (CaF₂, c) = -292.9 and -293.1 kcal/mol.

Guntz (19) made measurements on the neutralization of $\text{Ca}(\text{OH})_2(\text{aq})$ and HF(aq) which yield ΔH_f° (CaF₂, c) = -293.1 kcal/mol, according to Parker (2).

A median value of ΔH_{298}° (CaF₂, c) = -293 ± 1.5 kcal/mol is adopted.

Heat Capacity and Entropy

Huffman and Norwood (8) have measured the low temperature heat capacity in the range 3.6° to 30°K . Eucken and Schwes (7) in the range 17° to 86°K and Todd (9) from 50° to 296.5°K . We have fitted a smooth polynomial curve through the data of references 6 and 8 and this yields $S_{298}^\circ = 16.39 \pm 0.08$ eu based on $S_{298}^\circ = 0.0002$ eu. The values of reference 7 deviate considerably at the lowest temperatures but are in reasonable agreement at higher temperatures.

The high temperature enthalpy of calcium fluoride has been reported by Naylor (3) to 1788°K , Kestnikov and Karetnikov (10) to 1273°K , and Lyashenko (11) to 1490°K . All the data are in approximate agreement and the more extensive results of Naylor on a very pure sample are adopted. The heat capacities, below 1424°K were derived from a polynomial fit of the enthalpy data of the form $H = at^4 + bt^3 + ct^2 + d/T + e/T^2$.

Transition Data

The temperature of transition is that reported by Naylor (3), the large uncertainty has been assigned since at 1424°K the enthalpies indicate complete conversion to $\beta\text{-CaF}_2$, and the next lower point is at 1402°K . Evidence in support of a transition in this region comes from Lyashenko (11) whose plot indicates a break between 1273° and 1413°K . In addition, SrCl_2 which has the fluorite structure has a transition near the melting point. The enthalpy of transition is that reported by Naylor (3).

Melting Data

McCreary (12) reports the melting point of a 99.1% pure sample as $1687 \pm 5^\circ\text{K}$. Porter and Brown (13) report $1675 \pm 5^\circ\text{K}$ as the melting point of 99.8% pure CaF₂ and Rogers et al. (14) obtained 1684°K as the melting point. The adopted melting point is $1691 \pm 5^\circ\text{K}$, for a sample of natural fluorite of high purity, was reported by Naylor (3). The heat of melting, 7100 cal, is that measured by Naylor (3). Three determinations from high temperature phase diagrams give 7250 ± 350 cal (15), 5500 cal (16) and 9800 cal (14).

Sublimation Data

See the CaF₂(g) table for details.

Calcium Difluoride (CaF₂)

(Liquid) GFW = 78.0768

CALCIUM DIFLUORIDE (CaF₂)

(LIQUID)

GFW = 78.0768

 $S_{298.15}^{\circ} = 22.125$ gibbs/mol $\Delta H_{298.15}^{\circ} = -283.477 \pm 1.5$ kcal/mol $T_m = 1691 \pm 5^{\circ}\text{K}$ $\Delta H_m^{\circ} = 7.10 \pm 0.1$ kcal/mol $T_b = 2806.5 \pm 30^{\circ}\text{K}$ $\Delta H_v^{\circ} = 73.78 \pm 0.8$ kcal/mol

Heat of Formation

The heat of formation is obtained from that of the crystal by adding the heat of melting and the difference between $H_{1691} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived from the heat content measurements of B. F. Naylor, J. Am. Chem. Soc. 57, 150 (1943). The heat capacity is constant in the real liquid range but at 1000°K a glass transition is assumed below which it follows that of the crystal. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the crystal table for details.

Vaporization Data

The boiling point is calculated as the temperature at which $\Delta G = 0$ for the vaporization process. The heat of vaporization is the difference in $\Delta H_{T_b}^{\circ}$ between liquid and gas.

Dec. 31, 1968

Vibrational Frequencies and Degeneracies

ω , cm ⁻¹	Points	2nd law	3rd law	Drift
1463	1668	9	106.2 ± 3.7	105.66 ± 0.9
1246	1498	6	99.6 ± 2.5	106.00 ± 1.0
1421	1689	34	102.4 ± 0.3	104.00 ± 0.2
1823		1	106.4	106.4
2086	2208	7	106.7 ± 4.8	105.22 ± 0.5
1242	1669	19	104.7 ± 0.5	-0.7 ± 2.2

$\Delta H_{298.15}^\circ = 1.2836 \times 10^{-114} \text{ g}^{-3} \text{ cm}^6$
 Bond Distance: Ca-F = 2.1 Å
 Bond Angle: F-Ca-F = 135 ± 7°
 Product of the Moments of Inertia: $I_A I_B I_C = 1.2836 \times 10^{-114} \text{ g}^{-3} \text{ cm}^6$
 $\sigma = 2$

The heat of formation is obtained from that of the crystal by adding $\Delta H_{298.15}^\circ$. The vapor pressure data of five authors was analysed by 2nd and 3rd law methods to give $\Delta H_{298.15}^\circ$ as listed below. Note that the drifts are small and both positive and negative confirming the correctness of the functions used.

Reference	Range °K	Points	2nd law	3rd law	Drift
Freeman (1)	1463 - 1668	9	106.2 ± 3.7	105.66 ± 0.9	-0.2 ± 2.3
Blue et al. (2)	1246 - 1498	6	99.6 ± 2.5	106.00 ± 1.0	4.1 ± 2.0
Schulz and Searcy (3)	1421 - 1689	34	102.4 ± 0.3	104.00 ± 0.2	1.0 ± 0.2
Pottier (4)	1823	1	106.4	106.4	
Ruff and LeBoucher (5)	2086 - 2208	7	106.7 ± 4.8	105.22 ± 0.5	-0.7 ± 2.2
Blue et al. (2) *	1242 - 1669	19	104.7 ± 0.5		

* This set was not analysed by the third law since the absolute pressures were adjusted by the authors to match their weight loss values.

A median value of 105.5 ± 0.5 kcal/mol is adopted for the heat of sublimation which yields $\Delta H_{298.15}^\circ(\text{CaF}_2, \text{g}) = -187.5 \pm 2$ kcal/mol.

Heat Capacity and Entropy

The bond length was measured by Akishin and Spiridonov (6), but the diffraction patterns were interpreted as indicating a linear molecule. The vibrational frequencies and bond angle are those reported by Calder (7) using matrix isolation spectroscopy and isotopically enriched materials.

The individual moments are $I_A = 2.092 \times 10^{-39}$, $I_B = 2.3749 \times 10^{-38}$, and $I_C = 2.5840 \times 10^{-38} \text{ g cm}^2$.

June 30, 1970

D. E. Jensen (1) determined the heat of reaction $\Delta H_r^\circ = 35 \pm 10$ kcal/mol for $\text{Ca(g)} + \text{OH(g)} \rightarrow \text{CaOH}^+(\text{g}) + e^-$ in atmospheric pressure hydrogen-nitrogen-oxygen flames using the microwave cavity resonance method. This value was calculated assuming a bent model for CaOH; the value is not significantly changed, within the uncertainty, by the change in configuration. Combining ΔH_r° with JANAF heats of formation of Ca(g) and OH(g) and electron, we obtain $\Delta H_f^\circ(\text{CaOH}^+, \text{g}) = 87.7$ kcal/mol, which is adopted in the table. This corresponds to an ionization potential of 6.11 eV.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that gaseous NaOH, KOH, CaOH, RbOH are linear (2, 3, 4). This evidence also confirms the prediction of A. D. Walsh (5) that "HAB" molecules with 10 or less valence electrons (CaOH⁺ has 8 valence electrons) will be linear in their ground state. The molecule of CaOH⁺ has an isoelectronic structure of KOH.

The bond distances O-H and Ca-O are assumed to be the same as those in $\text{H}_2\text{O(g)}$ and CaO(g) , respectively (6, 7). The moment of inertia is 7.1284×10^{-39} g cm².

The Ca-O stretching frequency 733 cm⁻¹ is estimated from those of CaO(g) (8) and CaF(g) (9). The O-H stretching frequency, 3600 cm⁻¹, is estimated from those of $\text{H}_2\text{O(g)}$ (6) and $\text{CaOH}_2(\text{g})$ (10). The bending vibrational frequency, 370 cm⁻¹, is estimated by comparison with those of NaOH, KOH, RbOH (2, 4).

The enthalpy change between 0° and 298°K is 7.630 kcal/mol.

Heat of Formation

Cotton and Jenkins (1) determined the equilibrium constants in the temperature range 1570°K-2030°K for the reaction $\text{Ca}(g) + \text{H}_2\text{O}(g) \rightleftharpoons \text{CaOH}(g) + \text{H}(g)$ by atomic absorption spectroscopy in a fuel-rich hydrogen-nitrogen-oxygen flame. Using all JANAF functions, third law analyses of the data give $\Delta H_f^\circ_{298} = 13.8 \text{ kcal/mol}$ and the drift $1.9 \pm 2.9 \text{ eu}$. This leads to the heat of formation, $\Delta H_f^\circ(\text{CaOH}, g) = -53.3 \text{ kcal/mol}$ which is adopted in the tabulation. The bond dissociation energy, $D_0(\text{Ca-OH})$, is 104.6 kcal/mol .

Ryabova and Gurvich (2) reported the bond dissociation energy $D_0(\text{Ca-OH})$ as 100 kcal/mol . Schofield and Sugden (3) found $D_0(\text{Ca-OH})_2$ as $217 \pm 12 \text{ kcal/mol}$. Using the relation $D_0(\text{H-X})/D_0(\text{H-X})_2 = 0.47$ suggested by Kent, McDonald and Hargrave (4), we obtain $D_0(\text{Ca-OH}) = 102 \text{ kcal/mol}$.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that gaseous NaOH, KOH, CaOH and RbOH are linear (5, 6, 7). This evidence also confirms the prediction of A. D. Walsh (8) that "HAB" molecules with 10 or less valence electrons (CaOH has 9 valence electrons) will be linear in their ground state.

The ground state is assumed to be $^2\Sigma$ by analogy with isoelectronic CaF (9). The electronic levels are estimated from band spectra of CaOH reported by Gaydon (10).

The bond distances O-H and Ca-O are assumed to be the same as those in $\text{H}_2\text{O}(g)$ and $\text{CaO}(g)$, respectively (10, 11).

The moment of inertia is $7.1295 \times 10^{-39} \text{ g cm}^2$.

The O-H stretching frequency, 3600 cm^{-1} , is estimated from those of $\text{H}_2\text{O}(g)$ (10) and $\text{CaOH}(g)$ (12). The bending frequency, 320 cm^{-1} , is estimated by comparison with those of NaOH, CaOH and RbOH (5, 7). The Ca-O stretching frequency, 733 cm^{-1} , is estimated to be the same as that of $\text{CaO}(g)$ observed by Hultin and Lagerqvist (11) and Brewer and Hauge (13).

Heat of Formation

Bands in the visible for the $\text{Cl} - \text{Cl}^+$ transitions have been observed by A. Elliott, Proc. Roy. Soc. Soc. 32, 1517 (1936) have measured several lines in the same system. These data lead to a convergence limit of 20,831 ± 20 cm.⁻¹ from which the dissociation energy is obtained assuming excited and normal Cl atoms as the dissociation products of the A state. The assigned accuracy estimation reflects the uncertain knowledge of the products. The value in parenthesis is a precision measure and would apply if the dissociation products were those assumed. See R. G. Alkin and N. S. Baylis, Trans. Far. Soc. 33, 1333 (1937) for further details on the dissociation products.

Heat Capacity and Entropy

The electronic energy levels are listed by C. E. Moore, Nat. Bur. Stands. Circ. 467, (1949).

Heat of Formation.

The heat of formation was calculated from the equation Cl(g) - e⁻ → Cl⁺(g) with the JANAF auxiliary value for Cl(g); using an I.P. = 1.04931 X 10⁵ cm.⁻¹ (300.206 kcal/mole) obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, loc. cit. The electronic levels above 1 X 10⁵ cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The H^o-H₂₉₈^o value at 0°K. is -1.526 kcal./mole.

93750.639	3
94553.707	1
95399.870	3

Heat of Formation.

The heat of formation was calculated from the equation: Cl(g) + e⁻ → Cl⁻(g) with the JANAF auxiliary values for Cl(g); using the measured electron affinity = 3.613 e.v. (83.316 kcal./mole) obtained from R. S. Berry and C. W. Reimann, J. Chem. Phys. 39, 1540 (1963). Other calculated values for the electron affinity are: 3.70 e.v. reported by B. Edlen, J. Chem. Phys. 33, 98 (1960) and 3.56 e.v. reported by E. Clementi, A. D. McLean, D. L. Raimondi and M. Yoshimine, Phys. Rev. 133, A1274 (1964).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Argon. The electronic levels above 1 X 10⁵ cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The H°-H°₂₉₈ value at 0°K. is -1.481 kcal/mole.

CESIUM CHLORIDE (CsCl)

(CRYSTAL)

GFW = 168.358

S°_{298.15} = 24.183 ± 0.005 gibbs/molΔH°_{298.15} = -105.84 ± 0.2 kcal/mol

Tt(α-β) = 743°K

ΔH° = 0.90 kcal/mol

Tm = 918°K

ΔHm° = 3.8 kcal/mol

ΔH°_{298.15}(to monomer) = 48.74 kcal/mol

Heat of Formation

The heat of solution (ΔHsoln) of CsCl(c) in water has been measured by Forcand (1, 2), Haigh (3), Samoilov (4, 5), and Rodnikova (6). Based on their results, Parker (7) derived the corresponding ΔHsoln_{298.15}(∞ H₂O) values as 4.30, 4.32, 4.08, 4.25, 4.18 and 4.18 kcal/mol. Borob'ev (8) determined the same quantity and reported ΔHsoln₂₉₈(CsCl, ∞ H₂O) = 4.20 ± 0.04 kcal/mol. Using this value, 4.20 kcal/mol, and ΔH°₂₉₈ = -61.69 (9) and -39.952 kcal/mol (10) for Cs(∞ H₂O) and Cl⁻(∞ H₂O), respectively, we evaluate ΔH°₂₉₈(CsCl, c) = -105.84 ± 0.2 kcal/mol, which is adopted.

Heat Capacity and Entropy

Taylor (11) measured the low temperature heat capacities, 7.19 - 299.38°K, with an adiabatic calorimeter; the sample purity was >99.95 per cent. Employing these data we derive the value S°₂₉₈ = 24.183 eu based on S°₁₉ = 0.091 eu.

The high temperature enthalpies, 385.2 - 904.9°K, were measured by Kaylor (21, 22, 23), using a Bunsen ice calorimeter and a CsCl sample of 99.8 per cent purity. The heat capacities derived from the reported enthalpy data at temperatures 385.2 - 740.5°K appear too low (less than the adopted Cp's systematically by 0.9 gibbs/mol) to join smoothly with the low temperature data at 298°K. The Cp values derived from the measured enthalpy data in the temperature range 760 - 920°K increase rapidly from 14.46 to 16.3 gibbs/mol. In order to rationalize this situation, we adopt the high temperature heat capacities, 298 - 743°K, for CsCl(α) obtained by linear extrapolation of the low temperature data. The Cp values for CsCl(β) are adjusted such that the rate of increase in heat capacities is linear and less rapid than the original one, and the total enthalpy remains essentially unchanged. The discrepancy between the high and low temperature Cp for CsCl(α) may be caused by the incomplete β → α phase conversion involved. In order to resolve this discrepancy, independent enthalpy measurements using a high purity sample with composition well characterized before and after each drop experiment seem necessary.

Transition Data

The temperature of transition (in °K) has been reported by many investigators as 718 (14), 752 (15), 745 (16), 742 (21), 742.5 (12), 743 (20), and 733 (17), using different methods and samples of different purity. The value adopted is 743°K. The heat of transition (in kcal/mol) was reported to be 1.8 (14), 1.55 (18), 1.4 (19), 0.80 (22), 0.58 (12), 0.90 (13), and 1.1 (17). A median value 0.90 kcal/mol is tentatively adopted.

Melting Data

See CsCl(4) table for details.

Heat of Sublimation

ΔH°₂₉₈ is calculated as the difference between ΔH°₂₉₈ for CsCl(g) and CsCl(c).

(Liquid)

GFW = 168.358

CESIUM CHLORIDE (CsCl)

(LIQUID)

GFW = 168.358

$$S_{298.15}^{\circ} = 24.309 \text{ gibbs/mol}$$

$$\Delta H_f^{\circ} = -103.84 \pm 2.0 \text{ kcal/mol}$$

$$T_m = 918^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 3.8 \pm 1 \text{ kcal/mol}$$

$$T_b = 1597.3^{\circ}\text{K}$$

$$\Delta H_v^{\circ} = 27.52 \text{ kcal/mol of liquid (to equilibrium mixture)}$$

Heat of Formation

$\Delta H_f^{\circ}(s)$ is obtained from $\Delta H_f^{\circ}(c)$ by adding ΔH_m° and the difference between $H_{918}^{\circ} - H_{298}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy

The enthalpies of CsCl(l) at temperatures 923.6 - 1169.0°K were measured with a Bunsen ice calorimeter by Kaylor (1, 2). Dworkin (3) derived the heat capacity of CsCl(l) as 18.5 gibbs/mol from enthalpy data at temperatures 918 - 980°K. This value is adopted since it is in agreement with the enthalpy values reported by Kaylor et al. The heat capacity at temperatures above 1168 and below 923.6°K is assumed to be 18.5 gibbs/mol. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting temperature (in °K) of CsCl(c) has been determined by many investigators as 904 ± 3 (1), 919 (5), 912 (6), 911 (7), 918 (8), 916 (9), and 919 (13). The cause of the discrepancies is probably due to the difference in purity of the samples. The melting temperature adopted is 918°K.

The heat of melting (in kcal/mol) was reported to be 4.84 (14), 4.97 (15), 4.58 (10), 4.96 (11), and 4.78 (2), which were obtained calorimetrically. Using a modification of Kelley's method of obtaining heat of melting from freezing point data on binary systems involving CsCl (16), we derive the value of ΔH_m° as 3.6 - 4.0 kcal/mol, based on the following systems: CsCl-NaCl (5), CsCl-CuCl (9), CsCl-AgCl (9), CsCl-LiCl (9), and CsCl-Cs₃(PO₃)₃ (12). The heat of melting for CsCl(c) is tentatively adopted as 3.8 kcal/mol. The ΔH_m° values obtained calorimetrically are not used due to the uncertainties of the state of the sample before and after the enthalpy measurements.

Vaporization Data

T_b is the temperature at which the calculated total pressures of CsCl(g) and Cs₂Cl₂(g) equal one atmosphere. The vapor composition at T_b is derived as CsCl 80.4 per cent and Cs₂Cl₂ 19.6 per cent. The boiling point of CsCl(l) has been determined by several investigators as 1562 (17), 1572 (18), and 1576 (19). The heat required to vaporize one mole of liquid to the above vapor mixture at T_b is ΔH_v° .

Heat of Formation

The total pressures of CsCl(g) and $\text{Cs}_2\text{Cl}_2(\text{g})$ over CsCl(c) and CsCl(l) in the temperature range 605 - 1577°K have been determined by manometric, transpiration and Knudsen effusion methods by many investigators. Based on the reported results, the partial pressures of CsCl(g) and $\text{Cs}_2\text{Cl}_2(\text{g})$ are calculated using the derived free energy functions for CsCl(c), CsCl(l), CsCl(g) and $\text{Cs}_2\text{Cl}_2(\text{g})$, and the heats of sublimation and vaporization which are adjusted so that the sum of the calculated partial pressures of CsCl(g) and $\text{Cs}_2\text{Cl}_2(\text{g})$ approaches the measured total pressures, and the evaluated second and third law ΔH_f° values are in reasonable agreement. The results obtained are presented in the table below. The value of ΔH_f° (CsCl, g) adopted is -57.4 \pm 1 kcal/mol.

Gaydon (10) reported $D_0(\text{Cs-Cl}) = 4.6 \pm 0.2 \text{ eV}$ or $106.08 \pm 4.61 \text{ kcal/mol}$. Using this D_0 value and $\Delta H_f^\circ = 19.683$ and 28.52 kcal/mol for Cs(g) and Cl(g), we evaluate $\Delta H_f^\circ = -59.4 \pm 4.6 \text{ kcal/mol}$ for CsCl(g), which is in fair agreement with the adopted value.

Heat Capacity and Entropy

Clausen (11) studied the pure rotational spectra of CsCl(g) in the 0.36 - 3 mm range of the microwave region with the molecular-beam spectrometer, and derived the values of B_e , ω_e , $\omega_e x_e$, and r_e , which are adopted and corrected to the average isotopic species.

The Cs-Cl bond distance was measured as $3.06 \pm 0.03 \text{ \AA}$ by the electron diffraction method by Maxwell (12), which is not used. Similar values of B_e and ω_e were reported by Honig (13) and Rice (14), determined from microwave and infrared spectra, respectively. Barrow (15) gave $\omega_e = 240 \text{ cm}^{-1}$ (CsCl₃) which is significantly different from the adopted value 214.22 cm^{-1} for CsCl₃ and the value $209 \pm 6 \text{ cm}^{-1}$ reported by Rice (14). The moment of inertia is $3.924 \times 10^{-38} \text{ g cm}^2$.

 $T_m = 703^\circ K.$
 $\Delta H_f^0 = -35.0 \pm 0.4$ kcal. mole⁻¹
 $\Delta H_m^0 = 2.445$ kcal. mole⁻¹
 $\Delta H_g^0 = 54.77 \pm 0.5$ kcal. mole⁻¹ of monomer
 $\Delta H_g^0 = 37.2 \pm 0.2$ kcal. mole⁻¹ of trimer

Heat of Formation.

There have been three calorimetric determinations of the heat of formation. Thomsen, "Thermochemische Untersuchungen", Barth, Leipzig (1882-1886) reported -32.875 kcal. mole⁻¹. Berthelot, Ann. Chim. Phys. 20, 504 (1880) reported -35.6 kcal. mole⁻¹ and H. V. Wartenberg and H. Werth, Z. physik. Chem. A 151, 109 (1930) reported -32.1 ± 0.4 kcal. mole⁻¹. In addition, values of the heat of formation have been derived from several sets of equilibrium data. A. A. Noyes and M. Chow, J. Am. Chem. Soc. 40, 739 (1918) from a study of cell potentials derived a $\Delta H_f^0 = 7.19$ kcal. for the reaction $Cu(c) + HCl(aq) \rightarrow CuCl(c) + 1/2 H_2(g)$ which yields ΔH_f^0 298 (CuCl) = -32.76 kcal. mole⁻¹. Several investigators have studied the reaction $2CuCl(c) + H_2(g) \rightarrow 2Cu(c) + 2HCl(g)$ and its reverse reaction. These include A. B. Begdasarian, Trans. Am. Electrochem. Soc. 51, 449 (1927) who reported equilibrium constants which result in 2nd and 3rd law heats of reaction of 24.3 and 23.2 kcal. mole⁻¹; A. F. Kapustinsky, J. Am. Chem. Soc. 59, 460 (1936) who obtained similarly 20.1 and 21.8 kcal. mole⁻¹; S. A. Shchukarev and M. A. Oranskaya, Z. Obshch. Khim. 24, 1926 (1954) obtained 25.4 and 21.5 kcal. mole⁻¹ for the 2nd and 3rd law heat of reaction. These yield values for ΔH_f^0 298 (CuCl) ranging from -32.1 to -34.8 . M. Watanabe, Bull. Inst. Phys. Chem. Res. 9, 94 (1929) from cell studies reports ΔH_f^0 298 (CuCl) = -34.6 kcal. mole⁻¹. A value of ΔH_f^0 298 can also be obtained from ΔH_f^0 (CuCl)₃(g), which is fixed independently and known with good precision. Using the 3rd law heat of sublimation of CuCl(c) to trimer determined by D. W. Magee, Doctoral Thesis, Ohio State University (1955) [See trimer table], we obtain ΔH_f^0 298 CuCl(c) = -33.01 ± 0.3 kcal. mole⁻¹. A weighted average of -33.0 ± 0.4 kcal. mole⁻¹ was adopted.

Heat Capacity and Entropy.

The entropy of CuCl was obtained from the several pieces of equilibrium data reported above and the adopted ΔH_f^0 298. A weighted average of 20.8 ± 1 cal./mol.-deg) was adopted for S_{298}^0 CuCl(c). The enthalpy and heat capacity above 298°K. have been reported by A. N. Krestovnikov and G. A. Krestnikov, Jour. Gen. Chem. (USSR) 6, 955 (1936). However these values were not adopted since they do not give reasonable heat capacities and other data by these workers is not in agreement with established values. Heat capacities equal to those of AgCl, as given by K. K. Kelley, U. S. Bureau of Mines Bulletin 584, Washington 1960, were adopted here above 298°K.

Melting Data.

The temperature and heat of melting were those selected by K. K. Kelley, U. S. Bur. Mines Bulletin 393 (1936), from phase studies. The heat of melting was reported by Krestovnikov and Krestnikov loc. cit. as 2.54 kcal. mole⁻¹.

Sublimation Data.

The heat of sublimation was calculated from the adopted heats of formation at 298° for the reaction $x CuCl(c) \rightarrow (CuCl)_x(g)$ where $x = 1$ or 3. See the respective gas tables for details.

(to equilibrium mixture)}$

Heat of Formation.

Calculated from $\Delta H_f^{\circ} 298$ of the crystal plus ΔH_m° and the difference between $H_m - H_m^{\circ} 298$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated to be constant at 8 cal. deg.⁻¹ gm. atom⁻¹. The entropy was calculated in a manner analogous to that of the heat of formation.

Boiling Data.

The boiling point and heat of vaporization were calculated from the respective liquid, monomer and trimer gas tables. The boiling point was taken as the point where the total pressure reached 1 atm. At this point the partial pressures are 0.021 atm. of monomer and 0.979 atm. of trimer.

 $\sigma = 1$
 $r_e = 2.050$ Å
 $\alpha_e = 0.0001$ cm.⁻¹
 $B_e = 0.1761$ cm.⁻¹

Heat of Formation.

The heat of formation was obtained from the equilibrium data of I. Brewer and N. L. Lofgren, J. Am. Chem. Soc. 72, 3038 (1950). They studied the reaction $\text{Cu(c)} + \text{HCl(g)} \rightarrow \text{CuCl(g)} + \frac{1}{2} \text{H}_2\text{(g)}$ by measuring the amount of CuCl formed when various ratios of HCl:H₂ were passed over heated copper. Brewer and Lofgren analyzed the data by a least squares fitting technique and deduced partial pressures of monomer and trimer. The monomer pressures were subjected to second and third law analysis and gave $\Delta H_f^0 = 46.85 \pm 3.2$ and 43.83 ± 0.4 kcal. mole⁻¹ respectively. The 3rd law value yields $\Delta H_f^0 = 21.77 \pm 0.4$ kcal. mole⁻¹, which was adopted.

Heat Capacity and Entropy.

The molecular constants were corrected for normal isotopic abundance of both copper and chlorine and were calculated from the values for ⁶⁵Cu³⁵Cl given by R. K. Aundil, P. R. Rao and J. K. Brody, Nature 192, 444 (1961). The rotational constants were in good agreement with those reported by A. Lagerqvist and V. Lissarova-Girmanov for Cu⁶³Cl³⁵, Naturwissenschaften 48, 68 (1961).

Chlorine Monofluoride (ClF)

(Ideal Gas) Mol. Wt. = 54.4514

ClF

MOL. WT. = 54.4514

CHLORINE MONOFLUORIDE (ClF)

(IDEAL GAS)

Ground State Configuration $1\Sigma^+$
 $S_{298.15} = 52.064 \pm 0.01 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^0 = -12.12 \pm 0.6 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{298.15} = -12.14 \pm 0.6 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

State	ϵ_f , cm. ⁻¹	g_i
$1\Sigma^+$	0	1
$3\Pi^0$	19,592	1
$3\Pi_1$	19,592	2
$3\Pi_2$	19,592	2

$\lambda = 784.39 \text{ cm.}^{-1}$
 $\omega_e = 6.20 \text{ cm.}^{-1}$
 $\alpha_e = 0.004329 \text{ cm.}^{-1}$
 $\sigma = 1$
 $r_e = 1.62913 \text{ \AA}$

Heat of Formation

The $\Delta H_f^{298.15} = -12.14 \text{ kcal. mole}^{-1}$ was calculated from the dissociation energy ($D_0^0 = 58.99$) obtained from the visible band spectra measured by H. Schmitz and H. J. Schumacher, Z. Naturforsch. 2a, 359 (1947) and A. L. Wahrhaftig, J. Chem. Phys. 10, 248 (1941). The convergence limit of $21,512 \pm 20 \text{ cm.}^{-1}$ for the A state leads to the selected D_0^0 assuming that the products are $\text{Cl}(^2P_{3/2})$ and $\text{F}(^2P_{3/2})$ or to $D_0^0 = 60.36$ assuming $\text{Cl}(^2P_{3/2})$ and $\text{F}(^2P_{1/2})$. Calorimetric values bracket the two possibilities but more weight was given to the results of Wicke.

Method	Reaction	Observation
1 Spectroscopic	$\text{ClF} = \text{Cl}(^2P_{3/2}) + \text{F}(^2P_{3/2})$	$\Delta H_f^{298} \text{ kcal. mole}^{-1}$
2 Spectroscopic	$\text{ClF} = \text{Cl}(^2P_{3/2}) + \text{F}(^2P_{1/2})$	$D_0^0 = 58.99$
3 Calorimetric	$1/2 \text{ Cl}_2 + 1/2 \text{ F}_2 = \text{ClF}$	$D_0^0 = 60.36$
4 Explosion method	$1/2 \text{ Cl}_2 + 1/2 \text{ F}_2 = \text{ClF}$	$\Delta H_{293}^0 = -11.6 \pm 0.1$
5a Calorimetric	$\text{NaCl} + \text{ClF} = \text{NaF} + \text{Cl}_2$	$\Delta H_{290}^0 = -11.7$
5b Calorimetric	$\text{NaCl} + 0.5 \text{ F}_2 = \text{NaF} + 0.5 \text{ Cl}_2$	$\Delta H_{290}^0 = -24.5 \pm 0.5$
		$\Delta H_{290}^0 = -39.5 \pm 0.5$

*Based on $\Delta H_f^{298}(\text{NaCl}(c)) = -98.26$ and $\Delta H_f^{298}(\text{NaF}(c)) = -137.1 \text{ kcal. mole}^{-1}$

**Based on the difference between the two calorimetric reactions of reference 5a, 5b.

Heat Capacity and Entropy

The rotational constants were obtained from the microwave spectrum by D. A. Gilbert, A. Roberts and P. A. Orszold, Phys. Rev. 76, 1723 (1949) and by D. A. Gilbert and A. Roberts Phys. Rev. 77, 742 (1950). The vibrational constants were obtained from the analysis vibration-rotation fine structure in the infrared by A. H. Nielsen and E. A. Jones, J. Chem. Phys. 19, 1117 (1951).

The rotational and vibrational constants were adjusted to $\text{Cl}^{35} = 75.4\%$ and $\text{Cl}^{37} = 24.6\%$.

Point Group C_{2v} ΔH_f⁰ = [-135.6 ± 5] kcal. mole⁻¹

S_{298.15} = [82.76] cal. deg.⁻¹ mole⁻¹ ΔH_f⁰ 298.15 = [-136.0 ± 5] kcal. mole⁻¹

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω_e cm.⁻¹

[719](1)

[205](1)

[453](1)

Bond Distances: Mg-Cl = [2.18] Å Mg-F = [1.77] Å

Bond Angle: Cl-Mg-F = [170]°

Product of the Moments of Inertia: I_AI_BI_C = [1.5643 X 10⁻¹¹⁵] g.³ cm.⁶

Heat of Formation

The heat of formation is based on an estimated ΔH_f⁰ 298 = 0 for the reaction MgCl₂(g) + MgF₂(g) → 2MgClF(g), using ΔH_f⁰ 298.15 = -95.85 and -176.2 kcal. mole⁻¹ for MgCl₂(g) and MgF₂(g), respectively.

Heat Capacity and Entropy

The bond angle is taken to be the value we have adopted for MgCl₂(g). The Mg-Cl and Mg-F bond distances are assumed to be the same as those in MgCl₂(g) and MgF₂(g). The vibration frequencies are the averages of those for MgCl₂(g) and MgF₂(g). The three principal moments of inertia are: I_A = 0.0977 X 10⁻³⁵, I_B = 39.956 X 10⁻³⁹ and I_C = 40.054 X 10⁻³⁹ g. cm.²

ClF₂OP

MOL. WT. = 120.432

PHOSPHORYL DIFLUORIDE CHLORIDE (POClF₂)

(IDEAL GAS)

Point Group C_s
 $\Delta H_f^0 = [-226] \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 = 72.081 \text{ cal. deg}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^0 = [-228] \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 = 298.15$
Bond State Multiplicity = [1]

Vibrational Frequencies and Degeneracies	ω , cm ⁻¹	ω , cm ⁻¹	ω , cm ⁻¹
	274 (1)	424 (2)	948 (2)
	410 (1)	618 (1)	1358 (1)
		895 (1)	

Bond Distance: P-Cl = 2.01 ± 0.04 Å P-P = 1.51 ± 0.05 Å P-O = 1.55 ± 0.03 Å
Bond Angle: P-P-F = P-P-Cl = 103°
Product of the Moments of Inertia: I_AI_BI_C = 4.2790825 X 10⁻¹¹³ g.³ cm.⁶
 $\sigma = 1$

Heat of Formation.

The ΔH_f^0 298.15 of POClF₂ was estimated to be -228 kcal. mole⁻¹ from the ΔH_f^0 298.15 of POCl₃ by assuming bond energies of 120 kcal. for D(P-F) and 80 kcal. for D(P-Cl). The D(P-F) and D(P-Cl) values were taken from E. Neale and L. T. D. Williams, J. Chem. Soc., 2485 (1955) Part I and E. Neale, L. T. D. Williams and V. T. Moores, J. Chem. Soc., 422 (1956) Part II.

Essentially the same ΔH_f^0 298.15 may be obtained by assuming a $\Delta H_f^0 = 0$ for the following reaction:

Heat Capacity and Entropy.

The molecular constants were determined by L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc., 50, 1836 (1928) and by Q. Williams, J. Sheridan, and M. Gordy, J. Chem. Phys., 20, 164 (1952). Brockway and Beach used electron diffraction. Q. Williams et al. measured microwave spectra. Brockway and Beach assumed that the P-P-F and P-P-Cl angles were equal in POCl₂Cl and POClF₂. An analysis of Brockway and Beach's data by Q. Williams et al., indicates that the angles in POCl₂Cl, POClF₂, POCl₃, and POF₃ should be 103° rather than the reported 106° ± 3°. The principal moments of inertia calculated from these parameters were I_A = 3.24319 X 10⁻³⁸ g. cm.², I_B = 1.87015 X 10⁻³⁸ g. cm.², and I_C = 3.13496 g. cm.² X 10⁻³⁸.

The Raman spectra and vibrational frequencies for POCl₂Cl were reported by M. L. Delwaule and P. Francois, Compt. Rend. 222, 550 (1946). The frequencies were reassigned by M. L. Delwaule and P. Francois in J. Chim. Phys. 46, 87 (1949).

ClF₂OP

326 (1) 364 (1)

Bond Distances: Cl-F₁ = Cl-F₂ = 1.688 Å Cl-F₃ = 1.598 Å

Bond Angle: F₁-Cl-F₂ = F₂-Cl-F₃ = 67° 29' F₃-Cl-F₁ = 185° 02'

Product of Moments of Inertia: I_AI_BI_C = 2.6923061 X 10⁻¹¹⁴ g.³ cm.⁶

Heat of Formation: $\Delta H_f^{\circ} 298.15 = -37.97$ kcal. mole⁻¹ was calculated from $\Delta H_f^{\circ} 298 = 25.63$ kcal. mole⁻¹ obtained by third law analysis of the equilibrium data of H. Schmitz and H. T. Schumacher, Z. Naturforsch. **2b**, 362 (1947) for the reaction ClF₃(g) = ClF(g) + F₂(g). Similar values are obtained from the equilibrium data of K. Schafer and E. Wicke, Z. Elektrochemie **52**, 205-209 (1948). Calorimetric values scatter widely, as summarized below; these were given little weight.

Source	Method	Reaction	Observation ₂₁	3rd Law Drift	ΔH _f ²⁹⁸ (kcal. mole ⁻¹)
1a	K ₂ (523-623°K)	ClF ₃ (g) → ClF(g) + F ₂ (g)	ΔH _r ²⁹⁸ = 25.83	0.8 ± 0.3	-37.97
2a	K ₂ (735°K)	ClF ₃ (g) → ClF(g) + F ₂ (g)	ΔH _r ²⁹⁸ = 25.77	---	-37.91
2b	K ₂ (570-680°K)	ClF ₃ (g) → ClF(g) + F ₂ (g)	ΔH _r ²⁹⁸ = 26.12	6 ± 3	-38.28
1b	Calorimetric	3NaCl + ClF ₃ → 3NaF + 2Cl ₂	ΔH _r ²⁹¹ = -76.5	---	-40.02
1c	Calorimetric	NaCl + 0.5 F ₂ → NaF + 0.5 Cl ₂	ΔH _r ²⁹¹ = -59.5	---	-42.0*
3	Calorimetric	3NaCl + ClF ₃ → 3NaF + 2Cl ₂	ΔH _r ²⁹⁸ = -86.8	---	-29.7
4	Calorimetric	0.5 F ₂ + NaCl → NaF + 0.5 Cl ₂	ΔH _r ²⁹³ = -59.3	---	-31.1**
5	Flow reaction	0.5 Cl ₂ (g) + 1.5 F ₂ (g) = ClF ₃ (g)	ΔH _r ⁴⁷³ = -26.4	---	-26.4

*From combination of 1b and 1c. **From combination of 3 and 4.

Heat Capacity and Entropy.

The structural constants were obtained from the microwave study of D. P. Smith, J. Chem. Phys. **21**, 609 (1953). The planar distorted "m" structure is similar to that derived from X-ray studies of the solid by R. D. Burbank and P. N. Bensey, J. Chem. Phys. **21**, 802 (1953). Fundamental frequencies are taken from the infrared and Raman spectra of H. H. Claassen, B. Weinstein and J. G. Malm, J. Chem. Phys. **28**, 285 (1958). These data confirm the "m" structure as opposed to the pyramidal structure used in earlier spectral analyses.

Claassen, et al., loc. cit., calculate thermodynamic functions virtually identical with the JANAF values. These authors also correct the third law entropy reported by J. W. Gitsard, H. A. Bernhardt and G. D. Oliver, J. Am. Chem. Soc. **73**, 5725 (1951) from measurements of heat capacity (14-285°K.) and vapor pressure (228-303°K.). The entropy at the normal boiling point becomes $S_{284.91}^{\circ} = 67.04$ cal. deg.⁻¹ mole⁻¹ when a non-ideality correction consistent with the normal boiling point becomes $S_{284.91}^{\circ} = 67.04$ cal. deg.⁻¹ mole⁻¹. The corresponding statistical entropy, $S_{284.91}^{\circ} = 66.59$ cal. deg.⁻¹ mole⁻¹, is consistent with the third law value within the probable error in the entropy of the liquid and the entropy of vaporization. The three principal moments of inertia are: I_A = 6.114 X 10⁻³⁹, I_B = 1.61545 X 10⁻³⁸ and I_C = 2.42859 X 10⁻³⁸ g. cm.²

Chlorotrifluorosilane (ClSiF₃)
(Ideal Gas) Mol. Wt. = 120.547

Bond Angle: F-I-F = 90°

Product of Moments of Inertia: $I_{AB}I_C = 2.47289 \times 10^{-113} \text{ g}^3 \text{ cm}^6$

σ = 4

Heat of Formation.

The heat of formation was estimated by assuming that the ratio $[A.B.E.(ClF_3) - A.B.E.(ClF_3)]/[A.B.E.(ClF_3) - A.B.E.(ClF_5)]$ was equal to $[A.B.E.(BrF) - A.B.E.(BrF_3)]/[A.B.E.(BrF_3) - A.B.E.(BrF_5)]$, where A.B.E. represents average bond energy. All values were taken from these tables. A.B.E.(ClF₅) was thus calculated to be 36 kcal/mol which leads to $\Delta H_f^\circ = -57 \pm 15 \text{ kcal/mol}$.

Heat Capacity and Entropy.

O. M. Begun, W. H. Fletcher and D. P. Smith, J. Chem. Phys. 42, 2236 (1965), have reported the infrared spectra of the gas and the Raman spectra of the liquid. Their assignments have been adopted here, including one frequency ν_6 obtained from a valence force-field treatment. The values are consistent with those for IF₅(g) and BrF₅(g). D. P. Smith, Science 141, 1039 (1963), had previously reported three infrared bands. The structure of the molecule has not been determined but the spectra can only be interpreted assuming C_{4v} symmetry; this is in accord with IF₅ and BrF₅(g). Begun et al. assumed a square pyramidal structure with the chlorine in the base of the pyramid. There is some evidence that the chlorine may not lie in the basal plane but this would not appreciably affect the calculations. The structure adopted was that given by Begun et al. The individual moments of inertia are $I_A = I_B = 25.7380 \times 10^{-39} \text{ g cm}^2$ and $I_C = 37.3298 \times 10^{-39} \text{ g cm}^2$.

0	[200]
[200]	[8]
[1000]	[8]
[4000]	[8]

$\omega_e x_e = 1.19 \text{ cm.}^{-1}$
 $\omega_e = 404.92 \text{ cm.}^{-1}$
 $\omega_e = [0.17795] \text{ cm.}^{-1}$
 $r_e = [2.09]$

Heat of Formation.

The dissociation energy (D_0°) of FeCl(g) was reported as $3 \pm 2 \text{ e.v.}$ ($69 \pm 46 \text{ kcal. mole}^{-1}$) by A. G. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., London, 1953. The corresponding $\Delta H_f^{\circ} 298.15$ (FeCl, g) was evaluated to be $56 \pm 46 \text{ kcal. mole}^{-1}$. By comparing $D(\text{Fe-O}) = 101 \text{ kcal. mole}^{-1}$ in FeO(g) with the coordinate bond energies obtained in organic complexes and iron carbonyl halides of $E(\text{Fe-O}) = 59.4$ and $E(\text{Fe-Cl}) = 37.3 \text{ kcal. mole}^{-1}$, reported by M. M. Jones, B. J. Yow and W. R. May, Inorg. Chem. 1, 166 (1962), the $D(\text{Fe-Cl})$ in FeCl(g) was estimated as $101 \times (37.3/59.4) = 63.5 \text{ kcal. mole}^{-1}$, yielding $\Delta H_f^{\circ} 298.15$ (FeCl, g) = $64 \text{ kcal. mole}^{-1}$. The adopted value of $\Delta H_f^{\circ} 298.15$ for FeCl(g) is $60 \pm 20 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The ground state configuration, ω_e and $\omega_e x_e$ (corrected to the average isotopic species) were obtained from G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc., New York, 1950. The Fe-Cl bond distance was assumed to be the same as that in FeCl₂(g). Hence the values of B_e and ω_e were calculated. The electronic levels and quantum weights were estimated by comparison with the electronic levels in Fe²⁺(g) reported by C. E. Moore, "Atomic Energy Levels", Circular of the National Bureau of Standards 467, Vol. II, 1952, using the reasoning suggested by J. T. Hougen, G. E. Leroy and T. C. James, J. Chem. Phys. 35, 1670 (1961). The total 30 for the quantum weight was obtained from the ground multiplet of Fe²⁺ and was split arbitrarily. The entropy values may be in error by a few entropy units due to the uncertainties in the low lying electronic levels. The principal moment of inertia is $1.5728 \times 10^{-38} \text{ g. cm.}^2$.

Dec. 31, 1960; Mar. 31, 1961; Sept. 30, 1964

HYDROGEN CHLORIDE (HCl)

(IDEAL GAS)

Ground State Configuration $1\sigma +$ $\Delta F_f^0 = -22.019 \pm 0.05 \text{ kcal. mole}^{-1}$ $\Delta F_f^0 = -22.019 \pm 0.05 \text{ kcal. mole}^{-1}$ $\Delta F_f^0 = -22.019 \pm 0.05 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weights

ϵ_1 , cm. ⁻¹	ϵ_1	ϵ_1
0	1	1
$W_f X_e = 52.06 \text{ cm.}^{-1}$	$W_f X_e = 52.06 \text{ cm.}^{-1}$	$W_f X_e = 52.06 \text{ cm.}^{-1}$
$B_e = 10.5884 \text{ cm.}^{-1}$	$B_e = 10.5884 \text{ cm.}^{-1}$	$B_e = 10.5884 \text{ cm.}^{-1}$

Heat of Formation

The selected value, Rossini's flow calorimetric measurement (1) of the direct combination of the elements, is essentially the same as that in the revised version (2) of NBS Circular 500. JANAP analyses of the more recent measurements are summarized below, while the earlier measurements have been reviewed by Rossini (1).

Experimenters	Date	Method	References
Johnson, Ambrose	1963	Comparison of HCl, H ₂ SO ₄ and SO ₂ by solution calorimetry	2, 3, 4, 5, 6, 7, 8, 9, 10
Lecher, et al.	1949-52	Catalytic combination in flow calorimeter	11, 12
Roth, Richter	1934	Direct combination in bomb calorimeter	13
von Wartenberg, Hanisch	1932	Direct combination in flow calorimeter	14
Rossini	1932	Direct combination in flow calorimeter	1
- - -	1922-63	ΔF_f^0 from e.m.f. and ΔF_f^0 from statistical mechanics	15, 16, 17, 18, 19, 20
Lewis	1906	Equilibria for reaction $\text{HCl(g)} + \frac{1}{2} \text{O}_2(\text{g}) = \frac{1}{2} \text{H}_2\text{O(g)} + \frac{1}{2} \text{Cl}_2(\text{g})$	21

The direct combination values of Roth-Richter (13) and von Wartenberg - Hanisch (14) are 0.7% less negative than that of Rossini; however, all of the other methods favor the more negative value. The Roth - Richter value may be affected by errors in the measurement of the extent of reaction by HCl titration (9,22), since a set of experiments based on determination of the amount of H₂ gave a value of -22.02 kcal. mole⁻¹.

Rossini's value is confirmed by a variety of independent methods. The solution calorimetry (3), though it is related through a complex reaction scheme, is based on species which are now quite well known. E.m.f. measurements (15,16,17,18, 19,20) give $\Delta F_f^0 298.15 = -22.735$; assuming an uncertainty of 1.0 mv. in E° , this leads to $\Delta F_f^0 298.15 = -22.02 \pm 0.03$ when combined with the statistical entropies. The equilibria of Lewis (625-692°K) give $\Delta F_f^0 298.15 = -22.20 \pm 0.44$ (second law) and -22.30 ± 0.04 (third law).

Heat Capacity and Entropy

Spectroscopic constants for HCl³⁵ and HCl³⁷ were selected from the work of E. K. Flyler, E. D. Tidwell, Z. Elektrochem. 64, 717 (1960) and C. Haeuveler, P. Barchewitz, Compt. rend. 246, 3040 (1958). The values were adjusted to 75.5% HCl³⁵.

O-H distance = $0.98 \pm 0.01 \text{ \AA}$ O-Cl distance = $1.72 \pm 0.04 \text{ \AA}$ H-O-Cl angle = $104^\circ \pm 3^\circ$ $\sigma = 1$

Product of moments of inertia = $4.54 \times 10^{-117} \text{ g. cm.}^2$

Heat of Formation

I. E. Fils, K. P. Mikhchenko, and N. V. Pakhomova, Zhur. Neorg. Khim. 3, 1772, 1761 (1958), report the following heats of reaction:

$\text{ClO}^-(\text{aq}) + \text{H}^+(\text{aq}) \rightarrow \text{HCl}(\text{aq})$

$\Delta H_f^0 298.15 = -5.64 \pm 0.03 \text{ kcal.}$

$\Delta H_f^0 298.15 = -56.93 \pm 0.05 \text{ kcal.}$

If the following auxiliary heats of formation are used:

$\text{ClO}^-(\text{aq}) + \text{H}_2\text{O}_2(\text{aq}) \rightarrow \text{Cl}^-(\text{aq}) + \text{H}_2\text{O}(\text{l}) + \text{O}_2(\text{g})$

$\Delta H_f^0 298.15 = -40.02 \text{ kcal. mole}^{-1}$ (National Bureau of Standards Circ. 500, 1952)

$\Delta H_f^0 298.15 = -66.32 \text{ kcal. mole}^{-1}$ (National Bureau of Standards Circ. 500, 1952)

$\Delta H_f^0 298.15 = -45.70 \pm 0.02 \text{ kcal. mole}^{-1}$ (P. A. Giguère, B. G. Morissette, A. W. Olmos, and O. Knop, Can. J. Chem. 33, 804 (1955), consistent with $\Delta H_f^0 298.15$ of $\text{H}_2\text{O}_2(\text{g})$ in this compilation)

$\Delta H_f^0 298.15$ for $\text{HCl}(\text{aq})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. By averaging the heats of formation of $\text{H}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$, $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is estimated to be $-20 \pm 5 \text{ kcal. mole}^{-1}$. The value $-23 \pm 3 \text{ kcal. mole}^{-1}$ is adopted here.

$\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. By averaging the heats of formation of $\text{H}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$, $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is estimated to be $-20 \pm 5 \text{ kcal. mole}^{-1}$. The value $-23 \pm 3 \text{ kcal. mole}^{-1}$ is adopted here.

$\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. By averaging the heats of formation of $\text{H}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$, $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is estimated to be $-20 \pm 5 \text{ kcal. mole}^{-1}$. The value $-23 \pm 3 \text{ kcal. mole}^{-1}$ is adopted here.

$\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. By averaging the heats of formation of $\text{H}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$, $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is estimated to be $-20 \pm 5 \text{ kcal. mole}^{-1}$. The value $-23 \pm 3 \text{ kcal. mole}^{-1}$ is adopted here.

$\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. By averaging the heats of formation of $\text{H}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$, $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is estimated to be $-20 \pm 5 \text{ kcal. mole}^{-1}$. The value $-23 \pm 3 \text{ kcal. mole}^{-1}$ is adopted here.

$\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. By averaging the heats of formation of $\text{H}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$, $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is estimated to be $-20 \pm 5 \text{ kcal. mole}^{-1}$. The value $-23 \pm 3 \text{ kcal. mole}^{-1}$ is adopted here.

$\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. By averaging the heats of formation of $\text{H}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$, $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is estimated to be $-20 \pm 5 \text{ kcal. mole}^{-1}$. The value $-23 \pm 3 \text{ kcal. mole}^{-1}$ is adopted here.

$\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. By averaging the heats of formation of $\text{H}_2\text{O}(\text{g})$ and $\text{Cl}_2\text{O}(\text{g})$, $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is estimated to be $-20 \pm 5 \text{ kcal. mole}^{-1}$. The value $-23 \pm 3 \text{ kcal. mole}^{-1}$ is adopted here.

$\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$ is found to be $-31.35 \text{ kcal. mole}^{-1}$. From the heats of solution in water of other weak acids, $\Delta H_{\text{solution}}$ for HClO is estimated to be $-8 \pm 3 \text{ kcal. mole}^{-1}$. These heats yield $-23 \pm 3 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 298.15$ of $\text{HClO}(\text{g})$. AMMONIUM CHLORIDE (NH₄Cl)

(CRYSTAL)

MOL. WT. = 53.49158

$S_{298.15}^0 = 22.7 \pm 1.0 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_2 = 242.6^\circ \text{K.}$
 $T_1 = 457.7^\circ \text{K.}$
 $T_m = 795.2^\circ \text{K.}$
 $T_d = 612^\circ \text{K.}$

Heat of Formation.

The equilibrium pressures for the reaction $\text{NH}_4\text{Cl}(c) = \text{NH}_3(g) + \text{HCl}(g)$, at $320\text{--}625^\circ \text{K.}$, have been measured by many investigators. A. Smith and W. de Lange, *J. Chem. Soc.*, 2944 (1928), using the densi-tensimeter, determined the vapor pressure of $\text{NH}_4\text{Cl}(c)$ and the density of the saturated vapor simultaneously. The results obtained indicate that within the pressure $597\text{--}626^\circ \text{K.}$ the saturated vapor completely dissociates into gaseous NH_3 and HCl . Based on this conclusion, the reported vapor pressure data were employed to evaluate the heat of dissociation of $\text{NH}_4\text{Cl}(c)$ by both the second and third law methods. The results are presented as follows.

Investigator	Temperature, °K.	Second Law Value	Third Law Value	Drift, e.u.
Smith and Calvert (1)	521.6-619.1	43.18 ± 0.08	42.11	-2.0 ± 0.2
Smith and Lange (2)	527.9-625.6	42.15 ± 0.22	42.14	-0.2 ± 0.4
Braune and Knoke (3)	525.4-615.0	42.05 ± 0.08	42.05	-0.5 ± 0.2
Rodebush and Michalek (4)	471.3-557.0	42.43 ± 0.38	42.08	-0.3 ± 0.2
Wagner and Neumann (5)	535.0-632.4	42.83 ± 0.38	42.17	-4.9 ± 1.1
Markowitz and Boryta (6)	503.4-611.4	41.27 ± 0.39	42.12	1.3 ± 0.8

The value of ΔH_f^0 298.15 adopted is $42.15 \pm 0.10 \text{ kcal. mole}^{-1}$, yielding ΔH_f^0 298.15 ($\text{NH}_4\text{Cl}, c$) = $-75.8 \pm 0.20 \text{ kcal. mole}^{-1}$. The corresponding ΔH_f^0 298.15 value evaluated from solution data, selected by V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes", NSRDS-NBS2, National Bureau of Standards, is $42.06 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The heat capacities ($20.1\text{--}523.2^\circ \text{K.}$) of $\text{NH}_4\text{Cl}(c)$ have been measured by the following investigators: (1) R. Ewell, *Ann. Physik*, 45, 1213 (1914), $138\text{--}301^\circ \text{K.}$; (2) P. Simon, *ibid.*, 69, 241 (1922), $20.1\text{--}290.8^\circ \text{K.}$; (3) R. Klinkhardt, *ibid.*, 84, 167 (1927), $323.2\text{--}523.2^\circ \text{K.}$; (4) P. Simon, C. v. Simon and M. Neumann, *Z. phys. Chem.*, 129, 339 (1927), $204.5\text{--}275.8^\circ \text{K.}$; (5) W. T. Ziegler and C. E. Messer, *J. Am. Chem. Soc.*, 63, 2694 (1941), $107.2\text{--}320.2^\circ \text{K.}$; (6) R. Extermann and J. Weigle, *Helv. Phys. Acta*, 15, 455 (1942), $228.2\text{--}248.2^\circ \text{K.}$; and (7) M. M. Popov and G. L. Galchenko, *J. Gen. Chem.*, USSR, 21, 2489 (1951), $373.2\text{--}523.2^\circ \text{K.}$. These C_p data were plotted and a smooth C_p curve was drawn and adopted. The C_p values above 523°K. were obtained by graphical extrapolation of the previous C_p curve. $S_{298.15}^0$ was derived from the adopted low temperature data, based on $S_{20.1}^0 = 0.114 \text{ e.u.}$

Transition Data.

There are two transitions reported in the literature. The low temperature transition data (T_2 and ΔH_f^0) were derived based on the heat capacity ($107\text{--}320^\circ \text{K.}$) data reported by W. T. Ziegler and C. E. Messer, *loc. cit.*, in which the other T_2 values given by previous investigators were reviewed. The high temperature transition data (T_1 and ΔH_f^0) were taken from R. Klinkhardt, *loc. cit.*. However, ΔH_f^0 = 1030 and ΔH_f^0 463.5 = $1059.1 \pm 8.0 \text{ cal. mole}^{-1}$ were reported by E. C. Scheffer, *Proc. Acad. Sci. Amsterdam*, 24, 1513 (1915/16), and M. M. Popov and G. L. Galchenko, *loc. cit.*, respectively. M. M. Markowitz and D. A. Boryta, *loc. cit.* determined T_1 to be $459.5 \pm 0.5^\circ \text{K.}$

Melting Temperature.

T_m was obtained from H. Rassow, *Z. anorg. Chem.*, 114, 117 (1920), determined under pressure.

Decomposition Temperature.

The value of T_d was calculated as the temperature at which the vapor pressure of the decomposition products (NH_3 and HCl) equals 1 atm. By differential thermal analysis, T_d for $\text{NH}_4\text{Cl}(c)$ was determined to be 611.4°K. by M. M. Markowitz and D. A. Boryta, *loc. cit.*

1500	89.500	134.477	84.250	75.341	163.484	- 23.789

S_{298.15} = 44.02 ± 0.04 cal. deg.⁻¹ mole⁻¹
ΔH_f° = 2.3 ± 0.2 kcal. mole⁻¹

ΔH_f° 298.15 = -70.69 ± 0.30 kcal. mole⁻¹
T_f = 513.15°K
T_d = [513]°K.

Heat of Formation.

A. A. Gilliland and W. H. Johnson, J. Research Natl. Bur. Standards 65A, 67 (1961), and M. M. Birky and L. O. Hepler, J. Phys. Chem. 64, 686 (1960), have derived the heat of formation for NH₄ClO₄(c) from solution-calorimetric measurements. Their values are -70.74 ± 0.32 and -70.63 kcal. mole⁻¹, respectively. The mean of these is adopted here.

Heat Capacity and Entropy.

B. H. Justice and E. F. Westrum, private communication, April 1961, have measured the heat capacity from 5° to 350°K. The C_p values above 350°K were extrapolated. From the partial molar entropies of NH₄⁺(aq) and ClO₄⁻(aq) and the entropy of solution, Birky and Hepler, loc. cit., calculated a value of 43.6 cal. deg.⁻¹ mole⁻¹ for S_{298.15}. The fair agreement of this value with that derived from C_p suggests that there is no residual entropy at 0°K, as there would be if the NH₄⁺ ion had a random orientation.

Transition and Decomposition Data.

T_f and ΔH_f° were obtained (under a pressure of NH₃) by M. M. Markowitz, Foote Mineral Company, Exton, Pennsylvania (private communication, September 20, 1962). T_d was estimated from the report by M. M. Markowitz, loc. cit.

Heat of Formation

A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Ed., Chapman and Hall, London 1953, gives 23 ± 2.3 kcal for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants from K. Wieland Zeits. f. Elektrochemie 54, 761 (1960) were weighted according to their natural isotopic abundances. Rotational constants were estimated using equation III, 123 p. 108, G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. Bond length given by G. Herzberg (loc. cit.).

(CRYSTAL)

MOL. WT. = 162.3574

$\Delta H_f^0 = -8.699 \pm 0.025$ kcal. mole ⁻¹
$\Delta H_f^{298.15} = -8.466 \pm 0.025$ kcal. mole ⁻¹
$\Delta H_m^0 = 2.773 \pm 0.002$ kcal. mole ⁻¹
$\Delta H_m^{298.15} = 12.450$ kcal. mole ⁻¹

 $S_{298.15}^{298.15} = 23.405$ cal. mole⁻¹ deg.⁻¹ $T_m = 300.53^\circ\text{K.}$

Heat of Formation.

The heat of formation is that adopted by O. V. Calder and W. F. Giauque, J. Phys. Chem. 69, 2445 (1965) from an analysis of the equilibrium data of J. McMorris and D. M. Yost, J. Am. Chem. Soc. 53, 2247 (1932) and C. M. Beeson and D. M. Yost, J. Chem. Phys. 7, 44 (1939). This yielded a heat of formation of ICl(g), from which the heat of formation of ICl(c) was calculated by using the heat of vaporization determined by Calder and Giauque loc. cit.

Heat Capacity and Entropy.

The heat capacity has been measured by Calder and Giauque loc. cit. from 17-322°K. The entropy was calculated based on $S_{15} = 0.592$ cal. mole⁻¹ deg.⁻¹ Above 300° the heat capacity data was extrapolated smoothly.

Melting Data.

All data were measured by Calder and Giauque loc. cit.

IODINE MONOCHLORIDE (CII)

(LIQUID)

MOL. WT. = 162.3574

S_{298.15}° = 32.544 cal. mole⁻¹ deg.⁻¹
T_m° = 300.53°K.

ΔH_f° 298.15 = -5.72 ± 0.03 kcal. mole⁻¹
ΔH_m° = 2.773 ± 0.002 kcal. mole⁻¹

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH_m° and the difference between H_{300.53}-H_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity from 300.53 to 317.76°K. has been measured by G. V. Calder and W. P. Giauque, J. Phys. Chem. 69, 2443 (1965). Above 318°K. it was extrapolated in a smooth manner. The entropy was obtained in a manner analogous to the heat of formation.

$\Delta H_f^{\circ} 0 = 4.574 \pm 0.025 \text{ kcal. mole}^{-1}$

$\Delta H_f^{\circ} 298.15 = 4.184 \pm 0.025 \text{ kcal. mole}^{-1}$

$S_{298.15}^{\circ} = 59.145 \text{ cal. mole}^{-1} \text{ deg.}^{-1}$

Ground State Configuration $1 \Sigma^{+}$

Electronic Levels and Quantum Weight

$\epsilon_1, \text{ cm.}^{-1} \frac{g_1}{1}$

$\omega_e x_e = 1.450 \text{ cm.}^{-1}$

$\omega_e = 382.18 \text{ cm.}^{-1}$

$\sigma_e = 2.327 \text{ \AA}$

Heat of Formation.

The dissociation energy from spectroscopic measurements of ICl(g) has been summarized by W. H. Evans, T. R. Munson and D. D. Wegman, J. Res. Natl. Bur. Standards, 55, 147 (1955) from which they adopt $D_0^{\circ} = 49.64 \text{ kcal. mole}^{-1}$. J. McMorris and D. M. Yost, J. Am. Chem. Soc. 54, 2247 (1932) and C. M. Beeson and D. M. Yost, J. Chem. Phys. 1, 44 (1939) studied the equilibria $\text{NOCl} = \text{NO} + 1/2 \text{ Cl}_2$ and $\text{NO} + \text{ICl} = \text{NOCl} + 1/2 \text{ I}_2(\text{g})$ from which the equilibrium constant of $\text{ICl} = 1/2 \text{ Cl}_2 + 1/2 \text{ I}_2(\text{g})$ can be obtained. G. V. Calder and W. F. Giauque, J. Phys. Chem. 69, 2443 (1965) have used 3rd law analysis to obtain $D_0^{\circ} = 49.578 \pm 0.025 \text{ kcal. mole}^{-1}$. This value was adopted yielding $\Delta H_f^{\circ} 298 = 4.184 \pm 0.025 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The molecular and vibrational constants were obtained from G. Herzberg "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York 1950. The values were then adjusted for the normal isotopic abundance of chlorine.

Heat of Formation.

The heat of formation was calculated from the heat of hydrolysis of K(c), the heats of solution of HCl(g) and KCl(c), and the standard heat of neutralization of a strong acid and strong base. Extensive measurements are available for all these quantities. Values used in the calculation, in addition to the heat of formation for HCl(g), are summarized below.

Source	Reaction	ΔH_f° 298.15 (kcal.)
1,2,3,4	$\text{K(c)} + \text{H}_2\text{O(l)} \rightarrow \text{KOH}(\infty \text{H}_2\text{O}) + 1/2 \text{H}_2(\text{g})$	-46.966 ± 0.05
5,2,6	$\text{HCl(g)} \rightarrow \text{HCl}(\infty \text{H}_2\text{O})$	-17.86 ± 0.015
7	$\text{KCl}(\infty \text{H}_2\text{O}) \rightarrow \text{KCl(c)}$	-4.115 ± 0.010
7	$\text{KOH}(\infty \text{H}_2\text{O}) + \text{HCl}(\infty \text{H}_2\text{O}) \rightarrow \text{KCl}(\infty \text{H}_2\text{O}) + \text{H}_2\text{O(l)}$	-13.345 ± 0.025

Heat Capacity and Entropy.

Low temperature heat capacities were obtained from the data (2.8-275°K.) of W. T. Berg and J. A. Morrison, *Proc. Roy. Soc. (London)* A242, 467 (1957). Previous measurements scatter around the selected values and are in good agreement. These include P. G. Strelkov, E. S. Itskevich, V. N. Kostyukov, and G. G. Mirskaya (12-298°K.), *Zhur. Fiz. Khim.* 29, 845 (1954); K. Clausen, J. Goldmann, and A. Perlick (10-275°K.), *Z. Naturforsch.* 4a, 429 (1949); and J. C. Southard and R. A. Nelson (17-285°K.), *J. Am. Chem. Soc.* 55, 4865 (1933). For other less extensive data see the review by K. K. Kelley and E. G. King, *USNB Bulletin* 592, 1961. The entropy is based on the extrapolation $S_{2.8}^{\circ} = 0.0006$ cal./deg.-mole.

High temperature values are based on enthalpy data (373-1038°K.) from T. B. Douglas, private communication, U. S. Natl. Bur. Std., May 23, 1961. These values join smoothly with the low temperature values and are in excellent agreement with the enthalpy data (675-933°K.) of S. M. Skuratov and S. A. Lapushkin, *J. Gen. Chem. (USSR)* 21, 2465 (1951) and the adiabatic heat capacities (334-721°K.) of A. Mustajoki, *Ann. Acad. Scient. Fennicae, Series A, I*, 38, 7 (1951).

Melting Data.

The melting point and heat of melting are from Douglas, loc. cit. Values of $T_m = 1043^{\circ}$ and 1045°K. have been reported by E. Aukrust, B. Ejlorge, H. Flood, and T. Forland, *Ann. New York Acad. Sci.* 79, 830 (1960) and J. W. Johnson and M. A. Bredig, *J. Phys. Chem.* 62, 604 (1958), respectively. The heat of melting is confirmed by $\Delta H_m^{\circ} = 6.34$ kcal./mole obtained from enthalpy data by A. S. Dvorkin and M. A. Bredig, *J. Phys. Chem.* 64, 269 (1960) and $\Delta H_m^{\circ} = 6.4$ and 6.5 kcal./mole based on enthalpy and phase diagram studies of Aukrust et al., loc. cit., respectively.

POTASSIUM CHLORIDE (KCl)

(LIQUID)

MOL. WT. = 74.555

$S_{298.15}^o = 20.71$ cal. deg. ⁻¹ mole ⁻¹
 $T_m = 1044^oK.$
 $T_b = 1710^oK.$ (to equilibrium vapor)
 $T_b = [1750^oK.]$ (to monomer only)
 $\Delta H_f^{298.15} = -100.81$ kcal. mole ⁻¹
 $\Delta H_m^o = 6.282$ kcal. mole ⁻¹
 $\Delta H_v^o = 29.7$ kcal. mole ⁻¹ (equilibrium vapor)
 $\Delta H_v^o = [37.14]$ kcal. mole ⁻¹ (monomer)

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH_m^o and the difference between ($H_{1044}^o - H_{298}^o$) for the crystal and liquid.

Heat Capacity and Entropy.

The constant heat capacity, 17.59 cal./deg.-mole, was derived from enthalpy data (1053-1173°K.) of T. B. Douglas, private communication, U. S. Natl. Bur. Std., May 23, 1961. This value was extrapolated above and below the experimental range. A lower value of 16.7 cal./deg.-mole was derived by A. S. Dworkin, private communication, Oak Ridge National Laboratory, Dec. 1, 1964, from enthalpy data (1050-1110°K.) obtained in a heat of melting study. The entropy of the liquid was obtained in a manner analogous to the heat of formation.

Melting Data.

The melting point and heat of melting are from Douglas, loc. cit. Values of $T_m = 1043^o$ and $1045^oK.$ have been reported by E. Aukrust, B. Bjorge, H. Flood, and T. Forland, Ann. New York Acad. Sci. 79, 830 (1960) and J. W. Johnson and M. A. Bredig, J. Phys. Chem. 62, 804 (1958), respectively. The heat of melting is confirmed by $\Delta H_m^o = 6.34$ kcal./mole obtained from enthalpy data by A. S. Dworkin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960) and $\Delta H_m^o = 6.4$ and 6.5 kcal./mole based on enthalpy and phase diagram studies of Aukrust et al., loc. cit., respectively.

Vaporization Data.

T_b (to equilibrium vapor) is the temperature resulting in unit total pressure based on the calculated partial pressures of KCl(g) and K₂Cl₂(g). This value may be compared with boiling points of 1698° and 1690°K. observed respectively by O. Ruff and S. Magdan, Z. anorg. allgem. Chem. 117, 147 (1921), and H. von Wartenburg and F. Albrecht, Z. Elektrochem. 27, 162 (1921). ΔH_v^o (equilibrium vapor) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 22.3 mole percent of dimer. According to the selected functions, the amount of dimer at lower temperatures increases gradually to about 32 mole percent at the melting point then decreases rapidly over the crystal. T_b (to monomer only) is taken as the temperature at which the calculated free energy change is zero for KCl(l) → KCl(g), while ΔH_v^o (monomer) is the corresponding heat of reaction.

Data on vapor pressures and dimer-monomer equilibrium are reviewed on the tables for KCl(g) and K₂Cl₂(g), respectively.

Heat of Formation.

The heat of formation was calculated from that of the liquid based on $\Delta H^{\circ}_{298.15} = 49.5 \text{ kcal./mole}$ as selected from vapor pressure analyses summarized below. Partial pressures for the monomer were obtained from data of the first four sources by combination of total vapor pressures with PVT data or with transpiration data. Mass spectrometric values (source 5) are based on temperature variation of ion intensity. These same five studies were used in selection of $\Delta H^{\circ}_{298.15} = 45.0 \text{ kcal./mole}$ for the dimer-monomer equilibrium (see K_2Cl_2).

The resulting tables were tested by comparison with total pressure data over the range 819-1691°K. Dimer-monomer ratios calculated from the tables were used to convert observed total pressures to the monomer pressures which are analyzed below (sources 6-11). The results are consistent except near the boiling point where the observed pressures (sources 10 and 11) are 6-18 percent larger than those calculated. Knudsen effusion and transpiration studies over the crystal were not analyzed since they are in essential agreement with the torion effusion data of source 6.

Heat Capacity and Entropy.

Rotational and vibrational constants are based on the microwave studies of P. L. Clouser and W. Gordy, Phys. Rev. 134, 4863 (1964). Earlier microwave data of A. Honig, M. Mandel, M. L. Storch, and C. H. Townes, Phys. Rev. 95, 629 (1954) and electric resonance data of C. A. Lee, B. P. Fabre, R. O. Carlson, and I. I. Rabi, Phys. Rev. 92, 1395 (1953) are in excellent agreement. Infrared spectra of S. A. Rice and W. Klemperer, J. Chem. Phys. 21, 573 (1957) yield $\omega_e = 281.6 \text{ cm.}^{-1}$ which is also in good agreement. The constants were adjusted to a natural isotopic composition of 24.47% ^{37}Cl and 6.8% ^{41}K .

C/K

ΔH_f°	$-100.9 \text{ kcal. mole}^{-1}$
ΔH_f°	$-102.6 \pm 1.0 \text{ kcal. mole}^{-1}$
ΔH_f°	$3.29 \text{ kcal. mole}^{-1}$
ΔH_f°	Unknown
T_m	798°K.
T_b	572.7°K.
T_g	$361 \pm 0.2 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

Heat of Formation.

The heat of decomposition of $\text{KClO}_4(c)$ to $\text{KCl}(c)$ and $\text{O}_2(g)$ was measured by W. H. Johnson and A. A. Gilliland, J. Res. Natl. Bur. Std., 63 (1961), yielding $\Delta H^\circ_{298.15} = -103.22 \pm 0.15 \text{ kcal. mole}^{-1}$. K. A. Hofmann and F. H. Marin, Stöber, preuss. Akad. Wiss. Physik. Math. Kl. 448 (1932), burned a mixture of persulfur and potassium perchlorate and obtained $\Delta E_{298.15} = -1.73 \text{ kcal. mole}^{-1}$ for the constant volume process corresponding to the reaction: $\text{KClO}_4(c) = \text{KCl}(c) + 2\text{O}_2(g)$. Correction of their value for ΔP° gives $\Delta H^\circ_{298.15} = -0.55 \text{ kcal. mole}^{-1}$ which agrees reasonably well to the corresponding value, $-0.96 \pm 0.10 \text{ kcal. mole}^{-1}$, reported by W. H. Johnson and A. A. Gilliland, loc. cit. However, for the same reaction, $\Delta H^\circ_{298.15} = -2.55 \pm 0.18 \text{ kcal. mole}^{-1}$ was determined by S. M. Skuratov, A. F. Vorob'ev and N. M. Privolova, Russ. J. Inorg. Chem. 17, 342 (1962). They measured this quantity by two different methods which gave results differing by 0.2 kcal. mole⁻¹. They measured $\pm 0.2 \text{ kcal. mole}^{-1}$. The value used here is the average of these four results. $\Delta H^\circ_{298.15}$ reported was $-101.9 \text{ kcal. mole}^{-1}$. The value used here is the average of these four results. M. Berthelot and P. Vieille, the heat of explosion of ammonium picrate between the heat of explosion of potassium picrate and that of an ammonium picrate-potassium perchlorate mixture, and also the difference between the heat of explosion of potassium picrate and that of a potassium picrate-potassium perchlorate mixture. They obtained $\Delta H^\circ_{298.15} = 7.5 \text{ kcal. mole}^{-1}$ for the reaction $\text{KClO}_4(c) = \text{KCl}(c) + 2\text{O}_2(g)$. From that the value of $\Delta H^\circ_{298.15}$ was calculated to be $-111.9 \text{ kcal. mole}^{-1}$. This value was not used.

Heat Capacity and Entropy.

The low temperature heat capacities ($12.53-298.0^{\circ}\text{K}$.) were measured by W. M. Latimer and J. E. Ahlberg, *J. Am. Chem. Soc.* **52**, 549 (1930). The heat capacities above 298°K . were estimated by comparison with those of $\text{NiCl}_2(\text{c})$. $S_{298.15}^{\circ}$ was reported by K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592 (1961), based on the low temperature heat capacities measured by W. M. Latimer and J. E. Ahlberg, loc. cit., using $S_{12.59}^{\circ}$ (extrap.) 0.14 cal. deg.⁻¹ mole⁻¹.

Transition Data.

T_c and ΔH_c° were obtained from the National Bureau of Standards, Circ. 500, "Selected Values of Chemical Thermodynamic Properties," by F. D. Rossini, et al., 1952.

Temperature of Melting.

^mT was taken from Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use," June 1949.

LITHIUM CHLORIDE (LiCl)

(CRYSTAL)

MOL. WT. = 42.397

$$\Delta H_f^{\circ} 298.15 = -97.578 \pm 0.273 \text{ kcal mole}^{-1}$$

$$S^{\circ} 298.15 = 14.173 \pm 0.015 \text{ cal deg}^{-1} \text{ mole}^{-1}$$

$$T_m = 883 \pm 2^{\circ}\text{K}$$

Heat of Formation

The heat of formation was obtained as follows:

- (1) $\text{LiOH} \cdot 100\text{H}_2\text{O} + \text{HCl} \cdot 100\text{H}_2\text{O} \rightarrow \text{LiCl} \cdot 201\text{H}_2\text{O}$
T. W. Richards and A. W. Rowe, *J. Am. Chem. Soc.*, **44**, 684 (1922).
- (2) $\text{Li}(c) + 100\text{H}_2\text{O}(l) + \text{LiOH} \cdot 100\text{H}_2\text{O} + 1/2 \text{H}_2(g)$
S. R. Gunn and L. G. Green, *J. Am. Chem. Soc.*, **80**, 4782 (1958).
- (3) $\text{LiOH} \cdot 100\text{H}_2\text{O} + \text{LiOH} \cdot 100\text{H}_2\text{O} + 900\text{H}_2\text{O}(l)$
T. W. Richards and A. W. Rowe, *J. Am. Chem. Soc.*, **43**, 770 (1921).
- (4) $1/2 \text{H}_2(g) + 1/2 \text{Cl}_2(g) \rightarrow \text{HCl}(g)$
JANAF Tables.
- (5) $\text{HCl}(g) + 100\text{H}_2\text{O}(l) \rightarrow \text{HCl} \cdot 100\text{H}_2\text{O}$
C. H. Slansky, *J. Am. Chem. Soc.*, **62**, 2430 (1940), and
J. H. Sturtevant, *J. Am. Chem. Soc.*, **62**, 3265 (1940).
- (6) $\text{LiCl} \cdot 201\text{H}_2\text{O} + \text{LiCl}(c) + 201\text{H}_2\text{O}(l)$
E. Lange and F. Dürr, *Z. phys. Chem.*, **121**, 361 (1926).

$$(1) + (2) + (3) + (4) + (5) + (6) \text{ gives Li}(c) + 1/2 \text{Cl}_2(g) \rightarrow \text{LiCl}(c)$$

A direct calorimetric determination by H. Siemensen and U. Siemensen, *Z. Electrochem.*, **56**, 643 (1952) gave -94.8 ± 0.6 kcal mole⁻¹. However, the solution route was thought to be inherently more accurate and was adopted.

Heat Capacity and Entropy

The heat capacity between 15° and 325°K has been measured by D. A. Shirley, *J. Am. Chem. Soc.*, **82**, 3861 (1960) and by F. L. Oetting, W. E. Hutton and G. C. Sinke, unpublished work, Thermal Laboratory, Dow Chemical Company. The two sets of data are in substantial agreement and were plotted together and used to evaluate the entropy at 298°. The extrapolation to 0°K was done assuming a T³ law and yielded S₁₅ = 0.019 e.u. Above 298° T. B. Douglas, J. L. Dever and A. W. Harman, quoted in Natl. Bur. Standards Report 6297, have made enthalpy measurements to 1200°K. E. N. Rodigina, K. Z. Gornelski, and V. F. Luginina, *Zhur. Neorg. Khim.*, **4**, 975 (1959) also made enthalpy determinations to 1100°K. These two sets of measurements were averaged and joined smoothly to the low temperature values.

Melting and Transition Data

The melting point has been reported as follows: 880°K., Douglas et al., loc. cit.; 883°K., Rodigina et al., loc. cit.; 883°K., H. M. Haendler, P. S. Bennett, and C. M. Wheeler, *J. Electrochem. Soc.*, **106**, 264 (1959); 879°K., H. Flood, O. Fyke, and S. Urnes, *Z. Electrochem.*, **59**, 364 (1955); 879°K., H. von Martenberg and H. Schulz, *Z. Electrochem.*, **27**, 566 (1921). The highest value of 883°K. was taken as representing the most pure samples. At this temperature the enthalpy equations of Douglas et al. yield a heat of fusion of 4.718 kcal mole⁻¹, those of Rodigina et al., 4.669 kcal mole⁻¹. A. S. Dworkin and M. A. Bredig, *J. Phys. Chem.*, **64**, 263 (1960) report a value of 4.76 ± 0.10 kcal mole⁻¹ and quote 4.83 kcal mole⁻¹ from a private communication from D. F. Smith. The average value ΔH_m = 4.74 ± 0.10 kcal mole⁻¹ was adopted.

A transition at 838°K has been reported by Kislova and Bergman, *Russ. J. Inorg. Chem.*, **5**, 1210 (1960) but is not supported by the enthalpy measurements quoted above.

LITHIUM CHLORIDE (LiCl)

(LIQUID)

MOL. WT. = 42.397

$$\Delta H_f^o 298.15 = -93.394 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^o = 16.745 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^o = 4.74 \pm 0.10 \text{ kcal. mole}^{-1}$$

$$T_m = 883 \pm 2^\circ \text{K}$$

$$T_b(\text{monomeric gas}) = 1701^\circ \text{K}$$

$$T_b(\text{equilibrium mixture}) = 1656^\circ \text{K}$$

Heat of Formation.

Obtained from that of the crystal by adding ΔH_m and $H_{883}^o - H_{298}^o(c)$ and subtracting $H_{883}^o - H_{298}^o(l)$.

Heat Capacity and Entropy.

The heat capacity from the melting point to 1100°K and 1200°K has been reported by E. N. Rodigins, K. Z. Gornitski, and V. F. Luginska, Zhur. Neorg. Khim. **4**, 975 (1959) and T. B. Douglas, J. L. Dever, and A. W. Harman, quoted in Natl. Bur. of Standards Report 6297. The equation given by the former authors for the enthalpy of the liquid does not agree with their measurements and has been replaced by $H_m - H_{298.15} = 18.000T - 1.5 \times 10^{-5}T^2 - 2279 \text{ cal. mole}^{-1}$, which fits to $\pm 0.5\%$. The two sets of results were averaged and the equations were assumed to hold up to the normal boiling point. The entropy was calculated from that of the crystal in a manner analogous to the heat of formation.

Melting.

See table for crystal.

Boiling.

The equilibrium boiling point was taken from H. von Wertenburg and H. Schultz, Z. Electrochem. **27**, 568 (1921) and the boiling point of the monomeric gas is defined as the temperature at which it reaches 1 atm. pressure. This was obtained from the free energy crossover between liquid and monomeric gas. The heat of vaporization to the monomeric gas was found from the tables to be 39.8 kcal. mole⁻¹.

LiClO₄

MOL. WT. = 106.397

(CRYSTAL)

LITHIUM PERCHLORATE (LiClO₄)

ΔH_f^o = Unknown

S_{298.15} = [30 ± 1] cal. deg⁻¹ mole⁻¹

ΔH_f^o 298.15 = -91.0 ± 0.7 kcal. mole⁻¹

ΔH_m^o = [7] kcal. mole⁻¹

T_m = 509°K.

Heat of Formation.

The heats of reaction (ΔH_f^o) involving LiClO₄(c) has been determined by several investigators as follows:

Investigator	Chemical Reaction	ΔH _f ^o 298.15, kcal. mole ⁻¹	ΔH _f ^o 298.15, kcal. mole ⁻¹
Gilliland and Johnson (1)	LiClO ₄ (c) + KCl(c) → LiCl(c) + KClO ₄ (c)	-5.86 ± 0.06	-90.34
Markowitz, et al. (2)	LiOH(225H ₂ O) + HClO ₄ (225H ₂ O) → LiClO ₄ (451H ₂ O) + H ₂ O(l)	-13.54 ± 0.09	-91.7
Birky and Hepler (3)	LiClO ₄ (c) → Li ⁺ (aq.) + ClO ₄ ⁻ (aq.)	-6.31 ± 0.13	-91.11

(1) A. A. Gilliland and W. H. Johnson, J. Res. Natl. Bur. Std. 65A, 67 (1961).

(2) M. M. Markowitz, R. F. Harris and H. Stewart, Jr., J. Phys. Chem. 63, 1325 (1959).

(3) M. M. Birky and L. G. Hepler, J. Phys. Chem. 64, 686 (1960).

The adopted value, ΔH_f^o 298.15 = -91.0 kcal. mole⁻¹, for LiClO₄(c) is the weighted average of the three values listed.

Heat Capacity and Entropy:

Heat capacities and S_{298.15} were estimated by comparison with those of KClO₄(c).

Melting Data.

T_m was obtained from T. W. Richards and H. H. Willard, J. Am. Chem. Soc., 32, 4 (1910). The value of ΔH_m^o 509 was estimated by comparison with the value, ΔH_m^o 528 = 5.4 kcal. mole⁻¹, for NaClO₃(c) reported by K. K. Kelley, Contribution to the Data on Theoretical Metallurgy, XIII. High-Temperature Heat-Content, Heat-Capacity and Entropy Data for the Elements and Inorganic Compounds, U. S. Bur. Mines Bull. 584 (1960).

$S_{298.15}^{\circ} = [39.245]$ cal. deg.⁻¹ mole⁻¹
 $\Delta H_f^{\circ} 298.15 = [-85.574]$ cal. deg.⁻¹ mole⁻¹
 $\Delta F_f^{\circ} = [7]$ kcal. mole⁻¹
 $T_m = 509^{\circ}\text{K}.$

Heat of Formation.

$\Delta H_f^{\circ} 298.15(1)$ was obtained from $\Delta H_f^{\circ} 298.15(c)$ by adding ΔH_m° and the difference between $H_{370.6}^{\circ}$ and $H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

C_p for LiClO₄(l) was estimated by comparison with that for NaClO₃(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting temperature (T_m) was obtained from T. W. Richards and H. H. Willard, J. Am. Chem. Soc., 32, 4 (1910). The value of $\Delta H_m^{\circ} 509$ was estimated by comparison with the value, $\Delta H_m^{\circ} 528 = 5.4$ kcal. mole⁻¹, for NaClO₃(c) reported by K. K. Kelley, Contribution to the Data on Theoretical Metallurgy, XIII. High-Temperature Heat-Content, Heat-Capacity and Entropy Data for the Elements and Inorganic Compounds, U. S. Bur. Mines Bull. 584 (1960).

0	1

$\omega_e = 462.4$ cm.⁻¹ $\sigma = 1$
 $\alpha_e = [0.0014]$ cm.⁻¹ $r_e = 2.199$ Å

Heat of Formation.

The heat of formation is calculated from $D_0^0 = 3.2$ e.v. reported by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Co., Inc., New York, 1950. $D_0^0 = 2.7 \pm 0.7$ e.v. reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", 2nd Edn., Chapman and Hall, London, 1953, yields ΔH_f^0 298 (MgCl, g) = 1.0 ± 16 kcal. mole⁻¹.

Heat Capacity and Entropy.

Spectroscopic constants were reported by Herzberg loc. cit. and adjusted for natural isotopic abundance. The bond length was reported by E. Morgan and R. P. Barrow, Nature 192, 1182, (1961). B_e and α_e were estimated by the method suggested by Herzberg loc. cit. The moment of inertia (I) is 11.578×10^{-59} g. cm.²

CIMG

(IDEAL GAS)

Ground State Configuration {¹Σ}

$S_{298.15}^{\circ} = [54.6 \pm 2] \text{ gibbs/mol}$

$\Delta H_f^{\circ} = 156 \pm 20 \text{ kcal/mol}$

$\Delta H_f^{\circ}_{298.15} = 156 \pm 20 \text{ kcal/mol}$

Electronic Levels and Quantum Weights

State	$\epsilon_i, \text{cm}^{-1}$	g_i

$3\Sigma_u^-$	[9000]	6
$1\Pi_u$	[11000]	2
$3\Sigma_g^-$	[20000]	3
1Δ	[25000]	2
$1\Sigma^+$	[30000]	1

$\omega_e x_e = [2] \text{ cm}^{-1}$ $\sigma = 1$

$B_e = [0.2415] \text{ cm}^{-1}$ $r_e = [2.2] \text{ \AA}$

Heat of Formation

The ionization potential of MgCl(g) was reported to be $7.2, 7.5 \pm 0.5$, and $7 \pm 1 \text{ eV}$ by Krasnov (1), Hildenbrand (2), and Beckett (2), respectively. The corresponding heats of formation at 298°K for MgCl(g) are derived as 156, 163, and 151 kcal/mol, using $\Delta H_f^{\circ}(\text{MgCl}, g) = -10.34 \text{ kcal/mol}$ from the JANAF MgCl(g) table (March 31, 1966). The value of $\Delta H_f^{\circ}_{298}$ for MgCl⁺(g) is tentatively selected as $156 \pm 20 \text{ kcal/mol}$.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as NaCl(g) which is isoelectronic with MgCl⁺(g). The six electronic states are obtained from Fougere (3). The corresponding electronic levels are estimated by comparison with the isoelectronic molecules BeS (4), BaO (5, 6), and HgO (5, 7). The bond distance is estimated by the method suggested by Krasnov (8). The values of ω_e and $\omega_e x_e$ are estimated by comparison with those for MgCl(g) and NaCl(g). B_e and α_e are calculated by the method recommended by Herzberg (5). The moment of inertia is $1.159 \times 10^{-38} \text{ g cm}^2$. The enthalpy at 0°K is -2.27 kcal/mol .

NITROSYL CHLORIDE (NOCl)

(IDEAL GAS)

MOL. WT. = 65.4591

Point Group C_∞ $\Delta H_f^o = 12.83 \pm 0.2$ kcal. mole⁻¹ $\Delta H_f^o = 298.15 \pm 0.2$ kcal. mole⁻¹ $S_{298.15}^o = 62.53$ cal. deg.⁻¹ mole⁻¹

Ground State Quantum Weight = 1

Vibrational Frequencies & Degeneracies

 ω , cm.⁻¹

1800 (1)

594.9 (1)

331.5 (1)

Bond Distance: N-Cl = 1.95 ± 0.06 ÅBond Angle: Cl-N-O = $114 \pm 3^\circ$ Product of the Moments of Inertia: $I_A I_B I_C = 2.278778 \times 10^{-115}$ g.³ cm.⁶ $\sigma = 1$

Heat of Formation.

The equilibrium constants for the reaction $2\text{NOCl}(g) = 2\text{NO}(g) + \text{Cl}_2(g)$ have been measured in the temperature range from 372° to 491° K. by C. M. Beeson and D. M. Yost, J. Chem. Phys. **2**, 44 (1938). Using the reported equilibrium constants, the heat of reaction (ΔH_r^o) has been calculated by both the second and the third law methods, as 16.33 ± 0.1 kcal. mole⁻¹ and 18.42 ± 0.1 kcal. mole⁻¹, respectively. The third law value is adopted to calculate the heat of formation of nitrosyl chloride (g) as $\Delta H_f^o = 12.37 \pm 0.2$ kcal. mole⁻¹.

Heat Capacity and Entropy.

The selected bond distances and angle were obtained from the microwave measurements by J. D. Rogers and D. Williams, J. Chem. Phys. **34**, 2195 (1961). J. A. A. Ketelaar and K. J. Palmer, J. Am. Chem. Soc. **59**, 2629 (1937), reported the bond distance N-Cl = 1.95 Å and the angle O-N-Cl = 116° by the electron diffraction method. These two are in good agreement. The three principal moments of inertia are $I_A = 0.995 \times 10^{-59}$, $I_B = 14.6885 \times 10^{-59}$ and $I_C = 15.6780 \times 10^{-59}$ g. cm.². The selected vibrational frequencies which were obtained from the infrared spectrum by L. Landau and W. H. Fletcher, J. Mol. Spectry. **4**, 276 (1960), have been modified to natural isotopic mixture. W. G. Burns and J. J. Bernstein, J. Chem. Phys. **18**, 1669 (1950), reported the vibrational frequencies as 1799, 592 and 332 cm.⁻¹.

J. S. Gordon, J. Chem. Eng. Data **7**, 82 (1962), has calculated the thermodynamic functions from 298.15° to 6000° K. by the method of R. E. Fennington and K. A. Kobe, J. Chem. Phys. **22**, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from Landau and Fletcher, loc. cit., and J. D. Rogers, W. J. Pietenpol and D. Williams, Phys. Rev. **85**, 431 (1951). These calculated functions have been adopted in the tabulation. Below 298° K. the rigid-rotator harmonic oscillator method was used to calculate the functions.

Bond Distances: N-Cl = 1.83 Å N-O = 1.21 Å

Bond Angles: O-N-O = 129.5° O-N-Cl = 115.25°

Product of Moments of Inertia: $I_A I_B I_C = 2.36688 \times 10^{-114} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The selected heat of formation was obtained from the recalculation of the heat of reaction $\text{ClNO}_2 + \text{NO} = \text{ClNO} + \text{NO}_2$ which has been measured calorimetrically as $-9.27 \text{ kcal. mole}^{-1}$ by J. Ray and R. Ogg, Jr., J. Chem. Phys. **33**, 168 (1959). Not only the thermal effects of $2\text{NO}_2 = \text{N}_2\text{O}_4$ but also $\text{NO} + \text{NO}_2 = \text{N}_2\text{O}_3$ (a minor one) have been considered in calculation. Using all JANAF auxiliary data for ClNO , NO , NO_2 , N_2O_3 and N_2O_4 , the recalculation gives $\Delta H_f^\circ = 2.90 \pm 0.4 \text{ kcal. mole}^{-1}$ for $\text{NO}_2\text{Cl(g)}$. For the reaction $\text{ClNO} + \text{H}_2\text{O}_2 = \text{ClNO}_2 + 2\text{NO}_2$ also measured by Ray and Ogg, loc. cit., the recalculation gives $\Delta H_f^\circ = 2.56 \pm 0.4 \text{ kcal. mole}^{-1}$.

H. Martin and E. Koshlein, Z. physik. Chem. **17**, 375 (1958), have determined kinetically the heat of reaction, $\Delta H_f^\circ = 2.75 \pm 0.1 \text{ kcal. mole}^{-1}$, for the reaction $\text{NO}_2 + \text{NOCl} = \text{NO} + \text{NO}_2\text{Cl}$ which gives $\Delta H_f^\circ = 1.90 \pm 1 \text{ kcal. mole}^{-1}$ for $\text{NO}_2\text{Cl(g)}$. H. Cordes and H. Johnston, J. Am. Chem. Soc., **76**, 4264 (1954), have also determined kinetically the $\Delta H_f^\circ = 29.5 \text{ kcal. mole}^{-1}$ for the reaction $\text{NO}_2\text{Cl} = \text{NO}_2 + \text{Cl}$ which gives $\Delta H_f^\circ = 6.3 \pm 0.3 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The selected bond distances and bond angles were obtained from microwave spectrum studies by L. Clayton, Q. Williams and T. L. Weatherly, J. Chem. Phys. **30**, 1328 (1959). D. J. Millen and K. M. Simmott, J. Chem. Soc. **350** (1958), reported bond distance N-Cl = 1.840 Å, N-O = 1.202 Å and angle ONO = 130° 35' from the microwave measurement. These two are in good agreement.

The selected vibrational frequencies were obtained from infrared and Raman spectrum measurements by R. Ryanon and M. K. Wilson, J. Chem. Phys. **22**, 2000 (1954). However, the assignment of the fundamental frequencies has been revised by R. E. Dodd, J. A. Rolfe and L. A. Woodward, Trans. Faraday Soc. **52**, 145 (1956), and Y. Morino and T. Tanaka, J. Mol. Spectry. **15**, 179 (1965). Morino and Tanaka's assignment was adopted. The three principal moments of inertia are $I_A = 6.3568 \times 10^{-39}$, $I_B = 16.3809 \times 10^{-39}$ and $I_C = 22.7267 \times 10^{-39} \text{ g. cm.}^2$.

$$\Delta H_f^0 = -98.16 \pm 0.08 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{298.15} = -98.26 \pm 0.08 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = 6.73 \pm 0.04 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 17.24 \pm 0.05 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1073.8 \pm 1.0^\circ\text{K.}$$

Heat of Formation.

The heat of formation is based on $\Delta H_f^{298.15} = -57.39$ and $-39.95 \text{ kcal. mole}^{-1}$ for $\text{Na}^+(\infty \text{H}_2\text{O})$ and $\text{Cl}^-(\infty \text{H}_2\text{O})$, respectively, and on the heat of solution $\Delta H_{\text{sol}}^{298.15} = 0.922 \text{ kcal. mole}^{-1}$ for NaCl. These values were reported in a private communication from D. D. Wagman, National Bureau of Standards, June, 1964.

Heat Capacity and Entropy.

The low temperature values are based on the heat capacities (3-266°K) reported by T. H. K. Barron, A. J. Leadbetter, J. A. Morrison, Proc. Roy. Soc. (London) A279 (1376), 62 (1964). The earlier work of K. Clusius, J. Goldman, A. Perlick, Z. Naturforsch. 48, 424 (1949), results in a slightly higher entropy ($S_{298.15}^0 = 17.35 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$) but a lower heat capacity at room temperature ($C_p^{298.15} = 11.9 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$). The high temperature values have been obtained by reanalysis of the enthalpies (672 - 1279°K) of R. Dawson, E. B. Brackett, T. E. Brackett, J. Phys. Chem. 67, 1669 (1963), using the new value for $C_p^{298.15}$. The resulting tables agree within $\pm 0.1 \text{ kcal.}$ with the enthalpies (312 - 1058°K) of W. A. Roth, W. Bertram, Z. Elektrochem. 35, 38 (1929). The enthalpies (540 - 1037°K) of A. Magnus, Physik. Zeitschr. 14, 5 (1913), agree well at the lower temperatures but are about 0.3 kcal. smaller near the melting point.

Melting Data.

The melting temperature was taken from Dawson, Brackett and Brackett, loc. cit., and the heat of melting was obtained by reanalysis of their crystal and liquid enthalpies. Values of $T_m = 1073^\circ\text{K.}$ and $\Delta H_m^0 = 6.69 \pm 0.06 \text{ kcal. mole}^{-1}$ were reported by A. S. Dworkin, M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

Heat of Sublimation.

The vapor in equilibrium with NaCl contains both monomeric and polymeric forms (for details see the tables for NaCl gases).

Heat of Formation.

ΔH_f^o(l) was obtained from ΔH_f^o(c) by addition of ΔH_m^o and the difference between (H_{1073.8}^o - H_{298.15}^o) for the crystal and liquid.

Heat Capacity and Entropy.

These were obtained by analysis of the enthalpies (1076 - 1279°K) of R. Dawson, E. B. Brackett, T. E. Brackett, J. Phys. Chem. 67, 1669 (1963). The heat capacity was extrapolated to a constant value of 16.0 at the higher temperatures. A glass transition was assumed at 600°K. and below this temperature C_p was taken equal to that of the crystal.

Melting Data.

The melting temperature was taken from Dawson, Brackett and Brackett, loc. cit., and the heat of melting was obtained by reanalysis of their crystal and liquid enthalpies. Values of T_m = 1073°K. and ΔH_m^o = 6.69 ± 0.06 kcal. mole⁻¹ were reported by A. S. Dworkin, M. A. Bregie, J. Phys. Chem. 64, 269 (1960).

Heat of Sublimation.

The vapor in equilibrium with NaCl contains both monomeric and polymeric forms (for details see the tables for NaCl gases).

$\sigma = 1$

$r_e = 2.3606 \text{ \AA}$

Heat of Formation

The heat of formation is based on a heat of sublimation $\Delta H_g^0 = 54.9$ kcal. mole⁻¹ obtained from the more consistent sets of vapor pressure data by correction for the presence of dimer. Observed vapor pressures were converted to monomer pressures by use of dimer-monomer ratios calculated from JANAF free energy functions and $\Delta H_f^0 = 48.6$ kcal. for the reaction $(NaCl)_2(g) \rightarrow 2NaCl(g)$. Higher polymeric species were neglected. Analyses of the resulting monomer pressures are summarized below.

Heat of Sublimation
 $\Delta H_g^0 = 54.9$ kcal. mole⁻¹

Heat Capacity and Entropy.

Heat capacities and S°_{298.15} were estimated by comparison with those for NaClO₃(c) and KClO₄(c), respectively.

Transition Data.

T_c was reported in the National Bureau of Standards, Circ. 500, loc. cit. ΔH_c was estimated from that for KClO₄(c).

Temperature of Melting.

T_m was obtained from Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use," June 1949.

ΔH_f^o = Unknown

S°_{298.15} = [34] cal. deg.⁻¹ mole⁻¹

T_c = 581°K.

ΔH_c^o = [3.34] kcal. mole⁻¹

T_m = 755°K.

ΔH_m^o = Unknown

Heat of Formation.

A. A. Gilliland and W. H. Johnson, J. Res. Natl. Bur. Std. 65A, 67 (1961) measured the heat of solution of NaClO₄(c) and gave ΔH_f^o 298.15 = -91.48 ± 0.22 kcal. mole⁻¹ for NaClO₄(c). The heat of dilution of NaClO₄(c) was measured by C. E. Vanderveer and J. A. Swenson, J. Phys. Chem. 67, 285 (1963). The data led to ΔH_f^o 298.15 = -91.464 kcal. mole⁻¹ which agrees very well with the data reported by A. A. Gilliland and W. H. Johnson, loc. cit. The value of ΔH_f^o 298.15 was reported to be -92.18 kcal. mole⁻¹ in the National Bureau of Standards Circ. 500, "Selected Values of Chemical Thermodynamic Properties," 1952, based upon the data prior to 1950. A. P. Vorob'ev, et al., Proc. Acad. Sci. USSR, 135, 1439 (1960) measured the heat of decomposition of NaClO₄(c) into NaCl(c) and O₂(g) and gave ΔH_f^o 298.15 = -90.68 ± 0.3 kcal. mole⁻¹ for NaClO₄(c). The value reported by A. A. Gilliland and W. H. Johnson, loc. cit. was used.

Heat of Formation

R. A. Durie and D. A. Ramsay, Can. J. Phys. 35, 35 (1958) and G. Herzberg and D. A. Ramsay, Disc. Faraday Soc. 9, 80 (1950) report $D_0 = 22152 \pm 10$ cm.⁻¹ and $D_0 = 22141$ cm.⁻¹ respectively, and these values have been averaged.

Heat Capacity and Entropy

The spectroscopic constants are for the natural mixture of isotopes and are based on measurements by Durie and Ramsay, loc. cit., and by G. Porter, Disc. Faraday Soc. 9, 60 (1950). α_e has been estimated by the method given by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Company, Inc., New York, 1950, p. 108.

Sept. 30, 1963

TITANIUM OXIDE CHLORIDE (TiOCl)

(IDEAL GAS)

MOL. WT. = 99.357

Point Group [C_{2v}]ΔH°_f 0 = [-59.0] kcal. mole⁻¹S°_{298.15} = [62.992] cal. deg.⁻¹ mole⁻¹ΔH°_f 298.15 = [-58.4] kcal. mole⁻¹

Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

ω, cm. ⁻¹
[880] (1)
[230] (2)
[490] (1)

Bond Distances: O-Ti = [1.62] Å Ti-F = [2.17] Å

Bond Angles: O-Ti-Cl = [180°] C = 1

Rotational Constant: B₀ = [0.09225] cm.⁻¹

Heat of Formation.

ΔH°_f 0 was estimated as -58 kcal. mole⁻¹ by J. S. Gordon, Astronautics, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. ΔH°_f 298.15 was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. Principal moments were: I_A = I_C = 30.34 X 10⁻³⁹ g. cm.²

Heat of Formation

W. H. Evans, T. R. Munson, and D. D. Wagman, J. Research Natl. Bur. Standards **55**, 147 (1955), have evaluated the available data and chosen the above value.

Heat Capacity and Entropy

J. S. Gordon, private communication, February, 1961, has calculated the thermodynamic functions from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. **22**, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from J. B. Coon and E. Ortiz, J. Molec. Spectros. **1**, 61 (1957). The functions below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

June 30, 1963; Dec. 31, 1963

Ground State Configuration [$3\sum^-$]
 $\Delta H_f^0 = [34.7] \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 298.15 = [56.8] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^0 298.15 = [35.0] \text{ kcal. mole}^{-1}$

Electronic Levels and Multiplicities

ϵ_1 cm. ⁻¹	ϵ_2 [3]
0	

 $\omega_e = [472] \text{ cm.}^{-1}$ $\sigma = 1$ $\omega_e x_e = [1.89] \text{ cm.}^{-1}$ $x_e = [2.04] \text{ Å}$ $\alpha_e = [0.00098]$ $B_e = [0.2443]$

Heat of Formation.

The selected $\Delta H_f^0 298.15$ was calculated by assuming that the second and third bonds in $\text{PCl}_3(\text{g})$ are of equal strength, and that the first bond has a strength 20% greater than the other two. These assumptions were used by C. B. Henderson and R. S. Scheffee, Survey of Thermochemical Data, Atlantic Research Corporation, Alexandria, Virginia, January 1960. The selected $\Delta H_f^0 298.15$ was calculated using these bond strengths and auxiliary data from JANAP Tables.

A $\Delta H_f^0 298.15$, 40 kcal. mole⁻¹, estimated by C. J. O'Brien and J. R. Perrin, The Marquardt Corporation and J. Perrine, Olin Mathieson Chemical Corp., "Estimation of the Heats of Formation of Gaseous Combustion Product Molecules," WSC/CI Paper 58-4, October, 1959, when adjusted to the red V phosphorus reference state becomes [44.2] kcal. mole⁻¹.

A. A. Sandoval, H. C. Moser, and R. W. Kiser, J. Phys. Chem. 67, 124, (1963) have calculated a $\Delta H_f^0 298.15$ for PCl from an appearance potential. They selected the process $\text{PCl}_3 \rightarrow \text{Cl}^+ + \text{e}^- + \text{PCl} + \text{Cl}$ to explain this potential rather than the process $\text{PCl}_3 \rightarrow \text{Cl}^+ + \text{e}^- + \text{P} + \text{Cl}_2$. The reason for their selection was a calculated $\Delta H_f^0(\text{Cl})$, 10 kcal. lower than the literature value (See National Bureau of Standards "Selected Values of Chemical Thermodynamic Properties" Circular 500). Use of the JANAP $\Delta H_f^0 298.15$ for PCl_3 eliminates this difference.

Therefore, the process of the reported appearance potential would apparently be the second process which does not involve the neutral PCl radical.

Heat Capacity and Entropy.

The molecular constants were estimated by J. S. Gordon, Astrosystems International, Livingston, New Jersey, private communication, April 25, 1963.

 $B_e = [0.1029]$ cm⁻¹ $\alpha_e = [0.00048]$ cm⁻¹

Heat of Formation. $\Delta H_f^{298.15}$ was calculated from the dissociation energy of PbCl(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ω_e , and $\omega_e x_e$ were given by Herzberg, loc. cit. B_e , α_e , and ϵ were estimated by J. S. Gordon, Astrosystems, Inc., private communication, May, 1962.

Heat of Formation

The adopted value is based on $D_0^\circ = 90 \pm 15$ kcal/mol which is calculated from $D_0^\circ/D'(\text{LHX}) = 1.01$ and $D'(\text{LHX}) = 89$ kcal/mol. The latter value comes from linear Birge-Sponer extrapolation of ground state vibrational constants obtained by Verma (1). From the B'-X system. The ratio $D_0^\circ/D'(\text{LHX}) = 1.01$ is calculated from an empirical relationship proposed by Hildenbrand (2): $D_0^\circ/D'(\text{LHX}) = 0.365(r_e/x_e) + 0.448$ and $x_e = 14.40/(\text{IP-EA})$, where IP is the ionization potential of the more electronegative element and EA is the electron affinity of the more electronegative element. A similar calculation using $\omega_e/x_e = 2.1 \text{ cm}^{-1}$ obtained from the B-X system (2) would give $D_0^\circ = 98$ kcal/mol. These values for D_0° may be compared with average (per bond) heats of atomization of 101 kcal/mol for SiCl_2 and 94 kcal/mol for SiCl_4 .

Gaydon (3) selected $D_0^\circ = 7612$ kcal/mol on the assumption that $D_0^\circ/D'(\text{LHX}) = 0.8$, but Ovcharenko (4) suggested that this was too low by comparison with $D_0^\circ = 117$ kcal/mol obtained from the B' state. The latter value is calculated from $D'(\text{LHX}) = 33$ kcal/mol and presumes that $\text{Si}(\text{D})$ is the excited atomic product. The B and C states could also correlate to give values fairly consistent with $D_0^\circ = 117$. This interpretation seems unlikely, however, because it would involve a crossing of the potential curves for the B and B' states. Since the potential curves may be distorted due to the close proximity of the B and B' states, it seems preferable to obtain D_0° from constants for the ground state.

Heat Capacity and Entropy

Electronic levels of the B and C states are taken from the B-X and C-X systems reported by Ovcharenko et al. (5, 6). The A level is that assigned by Sanii (10) from analysis of the A-X system. The D level is that derived by Herzberg (7) from data of Jevons (8), but it is assigned as π as suggested by Verma (1). The B' level is from Verma and is confirmed by the earlier analysis of Ovcharenko (4). All vibrational and rotational constants for the ground state are those obtained by Verma (1) from the B'-X system. Values only slightly different were obtained from the B-X system by Ovcharenko (5, 6). The adopted constants are adjusted to the natural isotopic abundances of Si and Cl.

Heat of Formation

The heat of formation, ΔH_{f,298}⁰ of TiCl (g) is calculated from the dissociation energy, D₀⁰, which is estimated as 105 kcal/mol. This estimate is obtained from the relation D(TiCl) < D₀⁰(TiCl) < D(TiCl₂), where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF₂(g) by Zmbov and Margrave (1).

Extrapolations of the vibrational levels reported by Shenyavskaya (2), Rao (3) and Mace and Packer (4) yield values of the dissociation energy which are very low when considered with respect to bond energy relations.

Heat Capacity and Entropy

The vibrational frequency, ω_e, and anharmonic vibrational term, ω_ex_e, were reported by Shenyavskaya et al. (2). The interatomic distance is estimated from Guggenheimer's relation (5). B_e is calculated from r_e. The ground state term and electronic levels are estimated from the ground state multiplet of Ti³⁺(g). α_e is estimated from the Morse potential function.

TUNGSTEN MONOCHLORIDE (WCl)

(IDEAL GAS)

GFW = 219.303

Ground State Configuration [2]

 $\Delta H_f^\circ = 132.3 \pm 10$ kcal/mol $S_{298.15}^\circ = 62.6$ gibbs/mol $\Delta H_f^\circ = 132.3 \pm 10$ kcal/mol

Electronic Levels and Quantum Weights

ϵ , cm ⁻¹	g_i
0	[4]
[5000]	[2]
[15000]	[20]

 $\omega_e X_e = [455.4] \text{ cm}^{-1}$ $\sigma = 1$ $\omega_e = [1.46] \text{ cm}^{-1}$ $r_e = [2.26] \text{ \AA}$ $\alpha_e = [0.00042] \text{ cm}^{-1}$

Heat of Formation

The heat of formation, ΔH_f° (WCl, g) = 132.3 kcal/mol, is calculated from the bond dissociation energy, D_{298}° (W-Cl) = 100 ± 10 kcal/mol. This estimated D_{298}° is obtained from the average bond dissociation energy for WCl_x (g) + W(g) + xCl(g) where x = 2, 4, 5, 6, using all JANAF values.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in WCl₂(g). This distance is then used with Guggenheimer's relation for polar molecules to calculate the fundamental vibrational frequency ω_e (K. M. Guggenheimer, Proc. Phys. Soc. (London) 58, 456 (1944)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/4D_0 + 0.5 \omega_e = 0.0032$. The rotational constant B_e is calculated from the estimated bond distance. The value of α_e is calculated from the Morse potential function. The moment of inertia is $25.20 \times 10^{-39} \text{ g cm}^2$.

The ground state configuration, low lying electronic levels and their quantum weights are assumed to be the same as those estimated for Wf(g). See Wf(g) table (March 31, 1967) for details.

CIW

Zirconium Monochloride (ZrCl)

(Ideal Gas)

GFV = 126.673

ZIRCONIUM MONOCHLORIDE (ZrCl)

(IDEAL GAS)

GFV = 126.673

 $\Delta H_f^\circ = 49.3 \pm 5$ kcal/mol $\Delta H_{298.15}^\circ = 49.1 \pm 5$ kcal/molGround State Configuration $[4f]$ $S_{298.15}^\circ = [60.8 \pm 2]$ gibbs/mol

Heat of Formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among ZrCl, ZrCl₂, ZrCl₃ and ZrCl₄. Ion intensities were measured 2.5 eV above the ionization threshold. Using the reported equilibrium constants for the reaction ZrCl₃(g) + ZrCl(g) = 2 ZrCl₂(g) in the temperature range 1978-2274°K, second and third law analyses give the heats of reaction at 298°K as -10.36 and -12.83 kcal/mol, respectively. The third law drift is 1.4 ± 2.5 eu. Based on the third law ΔH_{298}° and ΔH_{298}° (ZrCl₂, g) = -44.5 kcal/mol (2), and ΔH_{298}° (ZrCl₃, g) = -125.3 kcal/mol (3), we obtain ΔH_{298}° (ZrCl, g) = 49.1 kcal/mol which is adopted in the tabulation.

Farber et al. (4) also studied mass spectrometrically the reaction Zr(c) + Cl(g) + ZrCl(g). They reported a second law heat of reaction, $\Delta H_{298}^\circ = 8.7 \pm 1.4$ kcal/mol. Using the equilibrium constants $K = I(\text{ZrCl})/I(\text{Cl})$ which we calculated from their reported ion intensities of run 3 in the temperature range 1667-1896°K, we obtain $\Delta H_{298}^\circ = 20.3$ kcal/mol by the third law method. The third law drift is 6.1 ± 2.4 eu. The heat of formation is derived as ΔH_{298}° (ZrCl, g) = 49.2 kcal/mol.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in ZrCl₄(g). The bond distance is then used with Guggenheimer's relation (5) for polar molecules to calculate the fundamental vibrational frequency ω_e . The anharmonicity correction x_e is estimated roughly by assuming $x_e = \omega_e/(v_e^2 + 0.5 \omega_e) = 0.0025$. The rotational constant B_e is calculated from the estimated bond distance. The value of a_e is calculated from the Morse potential function. The moment of inertia is 22.425×10^{-39} g cm².

The ground state configuration is taken from the ground state multiplet of Zr⁺ reported by Moore (6). The electronic levels and the quantum weights are estimated to be the same as those of Zr(fg).

CHLORINE, DIATOMIC (Cl₂) (IDEAL GAS - REFERENCE STATE)

MOL. WT. = 70.906

Ground State Configuration 1Σ⁺
S°_{298.15} = 53.29 ± 0.01 cal. deg.⁻¹ mole⁻¹
ΔH°_f 0 = 0
ΔH°_f 298 = 0

Electronic Levels and Multiplicities

State	E, cm. ⁻¹	E ₁
1Σ ⁺	0	1
3Π ⁺	18,147 ± 500	1
3Π ₁	17,841 ± 500	2
3Π ₂	17,560 ± 500	2

ω_e = 561.1 cm.⁻¹
ω_e x_e = 4.0 cm.⁻¹
B_e = 0.2408 cm.⁻¹
r_e = 1.986 Å
σ_e = 0.0017 cm.⁻¹
σ = 2

Heat of Formation.

The heat of formation (ΔH°_f) for Cl₂(g) is zero at all temperatures, by definition.

Heat Capacity and Entropy.

The functions adopted here were calculated by R. L. Fottler, J. Chem. Phys. 31, 1100 (1959) using a direct summation over the energy levels not including those of non-bonding states. The functions are for the naturally occurring isotopic composition.

The absorption spectrum of chlorine has been observed by A. Elliott, Proc. Roy. Soc. A 127, 638 (1930); C. P. Goodeve and B. A. Stephens, Trans. Faraday Soc. 32, 151.7 (1936); H. Stammreich, R. Fornieris and Y. Tavares, Spectrochim. Acta, 17, 775 (1961); Y. V. Rao and P. Venkateswarlu, J. Mol. Spectr. 9, 173 (1962); and A. E. Douglas, C. K. Møller and B. P. Stoicheff, Can. J. Phys. 41, 1174 (1963). There is disagreement over the vibrational assignments. The listed ground state spectroscopic constants for the naturally occurring isotopic composition are based upon the abundances given by D. Strominger, J. M. Hollander and G. T. Seaborg, Rev. Mod. Phys. 30, 585 (1958).

The molecular structure of gaseous chlorine was determined by the sector-microphotometer method of electron diffraction by S. Shibata, J. Phys. Chem. 57, 2256 (1963). The value of r_e(Cl-Cl) was found to be 1.986 Å. The other r_e values, 1.983 - 1.989 Å, were reported by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., Inc., 1950; W. G. Richards and R. F. Barrow, Proc. Chem. Soc., 297 (1962), and L. S. Bartell and K. Kuchitsu, presented at the International Conference on Magnetism and Crystallography, 1961, quoted by S. Shibata, loc. cit.

[141] (1)	[156] (1)

Bond Distance: Cs-Cl = [3.18] Å

Bond Angle: Cl-Cs-Cl = [93.2°]

Product of the Moments of Inertia: I_AI_BI_C = [3.8076 × 10⁻¹¹¹] g³ cm⁶

σ = [4]

Heat of Formation

Datz (1) studied the molecular association equilibrium in cesium chloride vapors by measuring the temperature dependence of the molecular weight of gaseous CsCl. The molecular weights were determined by measurement of the absolute pressure exerted by a known weight of completely vaporized salt contained in an isothermal fused silica bulb of known volume. The pressure sensing element was a fused silica manometer containing Au(t). Based on the reported results, we derive the equilibrium constants for the reaction Cs₂Cl₂(g) = 2CsCl(g) in the temperature range 1224 - 1418°K. The enthalpy change of this reaction is evaluated by the second and third law method as 39.3 ± 1.1 and 42.9 ± 0.6 kcal/mol, respectively. The drift in the third law value is equivalent to an entropy error of 2.7 ± 0.8 eu. Using the third law ΔHf° and ΔHf°₂₉₈ (CsCl, g) = -57.4 kcal/mol, we obtain ΔHf°₂₉₈ = -157.7 ± 2.5 kcal/mol for Cs₂Cl₂(g), which is adopted.

Schrier (2) determined the vapor pressures of molten cesium chloride at temperatures between 1165 and 1387°K by the boiling point or manometric method. The vapor analysis was performed using the transpiration method. An inert gas, N₂, was passed over the CsCl sample at a given temperature. The salt vapor entrained by the carrier gas was collected, weighed and analyzed. The data obtained were combined with the boiling point measurements to yield the average molecular weight of the vapor. Association into dimer was postulated. The mole fraction in the vapor and the partial pressure of CsCl(g) and Cs₂Cl₂(g) were calculated. The equilibrium constants, 1203 - 1350°K, for dissociation of the Cs₂Cl₂ dimer were derived. Using the reported equilibrium constants, we evaluate the enthalpy change (ΔHf°₂₉₈) of the reaction Cs₂Cl₂(g) = 2CsCl(g) to be 34.1 ± 2.9 and 43.2 ± 0.9 kcal/mol by the second and third law methods. Based on the third law ΔHf°₂₉₈ value and ΔHf°₂₉₈ (CsCl, g) = -57.4 kcal/mol, we obtain ΔHf°₂₉₈ = -158.0 kcal/mol for Cs₂Cl₂(g), which is in agreement with the adopted value.

Miller and Kusch (3) made an analysis of the velocity distribution of the CsCl molecules which escape through an ideal aperture from an isothermal enclosure. They found that there was no definite evidence that any species other than diatomic molecules were present in the beams in measurable amounts, in other words, the dimerization must be small, e.g. <1.5 per cent. However, according to our calculation the concentration of dimer is 15 - 34 per cent in the temperature range 600 - 900°K, and 33 - 20 per cent at the temperatures 1000 - 1600°K.

Heat Capacity and Entropy

The molecular structure is assumed to be planar, having D_{2h} symmetry. Based on the bond distances of Cs-Cs and Cl-Cl estimated by Berkowitz (4), the Cs-Cl bond distance and Cl-Cs-Cl bond angle are calculated. The vibrational frequencies were calculated by Berkowitz (5), on the basis of the potential function for an ionic model. The three principal moments of inertia are: I_A = 2.105 × 10⁻³⁷, I_B = 6.272 × 10⁻³⁷, and I_C = 2.732 × 10⁻³⁷ g cm².

COPPER DICHLORIDE (CuCl₂)

(CRYSTAL)

MOL. WT. = 134.446

$\Delta H_{f,0}^{\circ} = -49.39 \pm 1.5 \text{ kcal. mole}^{-1}$

$\Delta H_{f,298.15}^{\circ} = -49.2 \pm 1.5 \text{ kcal. mole}^{-1}$

$S_{298.15}^{\circ} = 25.833 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$T_d = [766]^{\circ}\text{K.}$

Heat of Formation.

S. A. Shchukarev and M. A. Oranskaya, Zhur. Obshchei Khim. 24, 1928 (1954) have reported equilibrium constants for the dissociation $\text{CuCl}_2(\text{c}) \rightarrow \text{CuCl}(\text{c}) + 0.5 \text{ Cl}_2(\text{g})$, which are in general agreement with earlier reports by P. Ephraïm, Ber. 50, 1089 (1917) and D. I. Tarasenko, A. I. Origorovich and A. V. Boroslovskaya, Collected Works of the Central State Institute for Non-Ferrous Metallurgy, Part 1, 2, 89 (1929). These data were subjected to third law analysis which revealed a significant trend of $13 \pm 0.5 \text{ cal. deg.}^{-1} \text{ mole.}$, indicating that equilibrium conditions were not reached. However an average value of $\Delta H_{f,298}^{\circ} = 16.5 \pm 1.9 \text{ kcal. mole}^{-1}$ yields a heat of formation of $\text{CuCl}_2(\text{c}) = -49.5 \pm 2.5 \text{ kcal. mole}^{-1}$ which is in good agreement with the adopted value taken from Natl. Bureau Std. Circular 500, Washington, 1952.

Heat Capacity and Entropy.

The low temperature heat capacity has been measured from 11-300°K. by J. W. Stout and R. C. Chisholm, J. Chem. Phys. 36, 979 (1962). The integration of this data from $S_{10}^{\circ} = 0.111 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ gave $S_{298}^{\circ} = 25.833 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$. The heat capacity above 298° was obtained by smooth extrapolation of the above data, since the heat capacities of A. N. Krestovnikov and G. A. Karetnikov, Journ. Gen. Chem. (USSR) 5, 955 (1956) were not compatible with the low temperature data.

Decomposition Data.

The temperature of decomposition was estimated from the table for $\text{CuCl}_2(\text{c})$, $\text{CuCl}(\text{l})$ and $\text{Cl}_2(\text{g})$ so that the pressure of Cl_2 is 1 atm.

Phosphoryl Fluoride Dichloride (POCl₂F)

Heat of Formation.

The ΔH_f^o 298.15 of POCl₂F was estimated to be -179 kcal. mole⁻¹ from the ΔH_f^o 298.15 of POCl₃ by assuming bond energies of 120 kcal. for D(P-F) and 80 kcal. for D(P-Cl). The D(P-F) and D(P-Cl) values were taken from E. Meale and L. T. D. Williams, J. Chem. Soc., 2485 (1955) Part I and E. Neale, L. T. D. Williams, and V. T. Moores, J. Chem. Soc. 422 (1956) Part II.

Essentially the same ΔH_f^o 298.15 may be obtained by assuming a ΔH_f^o = 0 for the following reaction:

Heat Capacity and Entropy.

The molecular constants were determined by L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc. 60, 1836 (1938) and by Q. Williams, J. Sheridan, and M. Gordy, J. Chem. Phys., 20, 164 (1952). Brockway and Beach used electron diffraction. Q. Williams et al. measured microwave spectra. Brockway and Beach assumed that the P-P-F and P-P-Cl angles were equal in POCl₂F and POCl₂F. An analysis of their data by Q. Williams et al. indicates that the angles in POCl₂F, POCl₂F, and POCl₂F should be 103° rather than the reported 106° ± 3°. The principal moments of inertia calculated from these parameters were I_A = 2.69184 X 10⁻³⁸, I_B = 3.79516 X 10⁻³⁸, and I_C = 4.60780 X 10⁻³⁸.

The Raman spectra and vibrational frequencies for POCl₂F were reported by M. L. Delvaux and P. Francois, Compt. Rend. 222, 550 (1946). These frequency assignments are summarized in J. Chim. Phys. 46, 87 (1949) by M. L. Delvaux and P. Francois.

$$\Delta H_f^0 = -82.32 \pm 0.12 \text{ kcal. mole}^{-1}$$
$$\Delta H_f^{298.15} = -81.70 \pm 0.12 \text{ kcal. mole}^{-1}$$
$$\Delta H_m^0 = 10.28 \pm 0.05 \text{ kcal. mole}^{-1}$$
$$\Delta H_m^{298.15} = 46.2 \pm 0.7 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 28.190 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$
$$T_m = 950^\circ \text{K.}$$

Heat of Formation.

The enthalpy change, $\Delta H_f^{298.15} = -4.06 \pm 0.05 \text{ kcal. mole}^{-1}$, for the reaction $\text{Fe}(\text{cl}) + 2(\text{HCl} \cdot 12.731 \text{ H}_2\text{O}) (\text{l}) = \text{FeCl}_2(\text{c}) + \text{H}_2(\text{g}) + 25.462 \text{ H}_2\text{O} (\text{l})$ was reported by M. F. Kohler and J. P. Coughlin, J. Phys. Chem. 63, 605 (1959). The value of $\Delta H_f^{298.15}(\text{FeCl}_2, \text{c})$ was then derived. The enthalpy change, $\Delta H_f^{298.15} = -19.5 \pm 0.2 \text{ kcal. mole}^{-1}$, for the reaction $\text{FeCl}_2(\text{c}) = \text{Fe}^{++}(\text{aq.}) + 2 \text{ Cl}^{-}(\text{aq.})$ was determined by J. C. M. Li and N. W. Gregory, J. Am. Chem. Soc. 74, 4670 (1952), yielding $\Delta H_f^{298.15} = -81.4 \pm 0.2 \text{ kcal. mole}^{-1}$ which is in agreement with the adopted value reported by M. F. Kohler and J. P. Coughlin. The equilibrium constants for the reaction $\text{FeCl}_2(\text{c}) + \text{H}_2(\text{g}) = \text{Fe}(\text{c}) + 2\text{HCl}(\text{g})$ were determined by W. Kangro and E. Petersen, Z. Anorg. Chem. 261, 157 (1950). By use of the second and third law methods the enthalpy change ($\Delta H_f^{298.15}$) of this reaction was evaluated as 37.81 ± 0.68 and $38.24 \text{ kcal. mole}^{-1}$, respectively. Based on the third law value for $\Delta H_f^{298.15}$, the value of $\Delta H_f^{298.15}(\text{FeCl}_2, \text{c})$ was derived to be $-82.37 \text{ kcal. mole}^{-1}$ which is in reasonable agreement with the adopted value.

Heat Capacity and Entropy.

The low temperature ($53.2-295.0^\circ \text{K.}$) heat capacities were determined by K. K. Kelley and G. E. Moore, J. Am. Chem. Soc. 65, 1264 (1943). The high temperature ($670.5-941.0^\circ \text{K.}$) heat capacities were measured by G. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943). The two sets of C_p data were plotted and joined smoothly at 298°K. The C_p values above 941.0°K. were obtained by graphical extrapolation. The C_p values, $60-500^\circ \text{C.}$, were also reported by P. L. Oetting and N. W. Gregory, J. Phys. Chem. 65, 138 (1961) which are in good agreement with those determined by G. E. Moore, loc. cit. $S_{298.15}^0$ was derived from the smoothed C_p values, using $S_{53.2}^0 = 4.950 \text{ e.u.}$ The $S_{298.15}^0$ value was determined by E. F. Westrum, Jr. quoted by L. E. Wilson and N. W. Gregory in J. Phys. Chem. 62, 437 (1958). The entropy at 298° is assumed to include the uncoupling energy of Fe^{++} which is calculated to be 3.2 e.u. which corresponds to R in 5.

Melting Data.

T_m and ΔH_m^0 were taken from G. E. Moore, loc. cit.

Heat of Sublimation.

The difference between $\Delta H_f^{298.15}$ for $\text{FeCl}_2(\text{g})$ and $\text{FeCl}_2(\text{c})$ is $\Delta H_m^{298.15}$. The former was obtained by the second and third law analyses on the equilibrium pressure data as described in $\text{FeCl}_2(\text{g})$ table.

$\Delta H_f^{298.15} = -74.411 \pm 0.13 \text{ kcal. mole}^{-1}$
 $\Delta H_m^{298.15} = 10.28 \pm 0.05 \text{ kcal. mole}^{-1}$
 $\Delta H_v^{298.15} = 29.83 \text{ kcal. mole}^{-1}$

Heat of Formation.

The value of $\Delta H_f^{298.15}(\text{FeCl}_2, l)$ was obtained from $\Delta H_f^{298.15}(\text{FeCl}_2, c)$ by adding $\Delta H_m^{298.15}$ and the difference between $H_m^{298.15} - H_{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity (850-1100°K.) for FeCl₂(l) was reported as 24.42 cal. deg.⁻¹ mole⁻¹ by O. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943). A constant C_p was assumed for all the other temperatures. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and $\Delta H_m^{298.15}$ were taken from G. M. Moore, loc. cit.

Vaporization Data.

The boiling point (T_b) is determined as the temperature at which the free energy change ($\Delta F_v^{298.15}$) for the reaction FeCl₂(l) = FeCl₂(g) approaches zero. The corresponding enthalpy change ($\Delta H_v^{298.15}$) at T_b is the heat of vaporization ($\Delta H_v^{298.15}$).

Heat of Formation.

The equilibrium pressures for the reactions (1) FeCl₂(l) = FeCl₂(g), (2) FeCl₂(c) = FeCl₂(g), and (3) Fe(c) + 2HCl(g) = FeCl₂(g) + H₂(g) were determined by several investigators. Using the reported data, the corresponding enthalpy changes (ΔH_f^o 298.15) for these reactions were evaluated by both the second and third law methods. Hence the respective ΔH_f^o 298.15 values for FeCl₂(g) were derived, based on the third law values for ΔH_f^o 298.15. The results obtained are presented as follows.

The value of ΔH_f^o 298.15 for FeCl₂(g) adopted is -35.5 ± 2.0 kcal. mole⁻¹.

Heat Capacity and Entropy.

The molecular structure, bond distance and angle, and two vibrational frequencies (ν₁ and ν₂) were obtained from L. Brewer, O. R. Sonayajulu and E. Brackett, Chem. Rev. **63**, 111 (1963). The electronic levels and quantum weights were estimated by comparison with the electronic levels in Fe²⁺(g) reported by C. E. Moore, "Atomic Energy Levels", Circular of the National Bureau of Standards 467, Vol. II, 1952, using the reasoning suggested by J. T. Hougen, O. E. Leroi and F. C. James, J. Chem. Phys. **34**, 1970 (1961). The total 2S for the quantum weight was obtained from the ground multiplet of Fe²⁺ and was split arbitrarily. The bending frequency (ν₃) was derived such that the calculated free energy functions are consistent with the experimental equilibrium data. In other words, the free energy functions were adjusted by choosing a proper value for ν₃ in order to make the second and third law values of ΔH_f^o for the reactions in reasonable agreement. The moment of inertia (I) is 5.125 x 10⁻³⁶ g. cm.².

Cl₂F₈

MERCURY DICHLORIDE (HgCl₂) (Crystal)

Mol. Wt. = 271.524

 $\Delta H_f^{298.15} = -55.000 \pm 1.0$ kcal. mole⁻¹ $S_{298.15}^{298.15} = [34.535] \pm 1.5$ cal. deg.⁻¹ mole⁻¹ $T_m = 550^\circ K$ $\Delta H_m = 4.64 \pm 0.05$ kcal. mole⁻¹

Heat of Formation. Taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," (1952).

Heat Capacity and Entropy. C_p was determined from the heat content data of L. E. Topol and L. D. Ransom, J. Phys. Chem. 64, 1339 (1960) and R. Ewald, Ann. d. Physik u. Chem. (4) 44, 1213 (1914).

Above 550° the curve was smoothly extrapolated. The entropy was estimated by adjusting the value to give the best fit of the melting, sublimation, and vaporization data.

Melting. T_m was taken from National Bureau of Standards Circular 500 (loc. cit.) ΔH_m was given by L. E. Topol and L. D. Ransom (loc. cit.).

Mercury Dichloride (HgCl₂)

MERCURY DICHLORIDE (HgCl₂) (liquid)

Mol. Wt. = 271.524
 ΔH_f^o 298.15 = -51.404 ± 1.0 kcal. mole⁻¹
 $S_{298.15}^o$ = [40.771] ± 1.5 cal. deg.⁻¹ mole⁻¹
 T_m = 550°K
 ΔH_m = 4.64 ± 0.05 kcal. mole⁻¹
 T_b = 577°K
 ΔH_v = 14.079 ± 0.25 kcal. mole⁻¹

Heat of Formation. Calculated from $\Delta H_f^o(c)$.

Heat Capacity and Entropy. The heat capacity was estimated to conform with the bromide and iodide, the value given by L. E. Topol and L. D. Ransom, J. Phys. Chem. 64, 1339 (1960) was counted. A glass type transition was assumed at 367°K below which the heat capacity was equal to that of the crystal. The entropy was obtained from $S^o(c)$, the entropy of fusion and the estimated heat capacity.

Fusion and Vaporization. T_m and T_b were taken from National Bureau of Standards (U.S.) Circular 500 (1952). ΔH_m was given by L. E. Topol and L. D. Ransom, J. Phys. Chem. 64, 1339 (1960) and ΔH_v was obtained from the data of E. B. R. Frideux, J. Chem. Soc. (London) 97, 2033 (1910) and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

MERCURY DICHLORIDE (HgCl₂) (Ideal Gas)

Mol. Wt. = 271.524
ΔH_f[°] 298.15 = -34.965 ± 1.5 kcal. mole⁻¹
S_{298.15}[°] = 70.433 cal. deg.⁻¹ mole⁻¹
Point Group D_{2h}

Vibrational Levels and Multiplicities

ω, cm. ⁻¹
380 (1)
70 (2)
415 (1)

Hg-Cl distance = 2.31 Å

Moment of Inertia = 62.022 X 10⁻³⁹ g. cm.²

σ = 2

Heat of Formation. The heat of formation of the crystal as given in National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952 was combined with the 3rd law heat of sublimation at 298°K from the data of K. Naka and Z. Shibata, J. Fac. Sci. Hokkaido Imp. Univ. Ser. III, 2, 183 (1958); R. Ruf and W. D. Treadwell, Helv. Chim. Acta 37, 1941 (1954) and P. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

Heat Capacity and Entropy. The vibrational constants were given by W. Klemperer and L. Lindeman, J. Chem. Phys. 25, 397 (1956). The bond length is a weighted average of the values given by H. Braune and S. Knoke Naturwiss. 21, 349 (1933); A. H. Gregg, G. C. Hampson, G. I. Jenkins, P. L. P. Jones and L. E. Sutton Trans. Farad. Soc. 33, 852, 1937; L. R. Maxwell and V. M. Morley Phys. Rev. 57, 21 (1940) and P. A. Akishin, V. P. Spiridonov and A. N. Knochchenkov, Zhur. Fiz. Khim. 33, 20 (1959).

Mercury Monochloride, Dimeric (Hg_2Cl_2)

MERCURY MONOCHLORIDE, DIMERIC (Hg_2Cl_2) (CRYSTAL)

MOL. WT. = 472.134

ΔH_f^0 298.15 = -63.319 ± 0.05 kcal mole⁻¹

$S_{298.15}^0$ = 46.017 cal deg⁻¹ mole⁻¹

$T_{\text{sub.}} = 655^\circ\text{K}$ (decomp.)

Heat of Formation

Based on the average free energy of formation, -50.315 kcal mole⁻¹, as measured by R. H. Gerke, J. Am. Chem. Soc. 44, 1684 (1922) and G. J. Hills and D. J. G. Ives, J. Chem. Soc. (London) 318, (1951), and the entropy of formation.

Heat Capacity

The data of F. Pollitzer, Zeits. f. Electrochemie 19, 513 (1913), from 22-199°K was treated by K. K. Kelley, U. S. Bureau of Mines Bulletin 592 (1960). The heat capacities listed by Kelley were raised by 0.06 to match the entropy data of Gerke (loc. cit.). Data above room temperature were obtained by smooth extrapolation.

Entropy

A mean value of the entropy of formation of -46.614 e.u. was adopted from the cell measurements of R. H. Gerke (loc. cit.).

Sublimation

The vapor pressure over mercurous chloride reaches 1 atmosphere at 655°K according to A. Smith and A. W. C. Menzies, J. Am. Chem. Soc. 32, 1541 (1910). At this point the vapor is dissociated into Hg(g) and HgCl₂(g).

Heat of Formation

The heat of formation is calculated from that of KCl(g) using ΔH_f²⁹⁸ = 45.0 kcal./mole for K₂O₂(g) → 2KCl(g) as selected from data analyses summarized below. The three experimental techniques include PVT measurements (source 1), combination of total vapor pressure and transpiration data (sources 2,3,4), and mass spectrometric studies of the variation of ion intensities with temperature (source 5). The results are reasonably consistent, considering the uncertainties inherent in the problem.

The resulting tables were tested by comparison with other data. Calculated total vapor pressures are in satisfactory agreement with the observed values over the range 820-1500°K.; however, near the boiling point they are lower by 6-18 percent [see KCl(g)]. Knudsen effusion data and transpiration data over KCl(c) have been reviewed by A. C. P. Pugh and R. F. Barron, Trans. Faraday Soc. 58, 671 (1958). These data suggest negligible dimer formation when combined with the total vapor pressures of V. Dietz, J. Chem. Phys. 4, 575 (1936). Calculated dimer formation (22 mole percent at 900°K.) agrees with the latter combination but calculated total pressures agree with those of Pugh & Barron. Velocity distribution studies of R. C. Miller and P. Kusch, J. Chem. Phys. 27, 961 (1957); 25, 860 (1956) suggest about 10 mole percent of dimer at 800°K. Thus, while minor inconsistencies do exist, it is not apparent that they exceed the combined experimental errors.

Heat Capacity and Entropy

The structure and vibrational frequencies are those calculated from an ionic model by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960); 22, 1386 (1958). The sixth fundamental was arbitrarily lowered from 206 to 100 cm.⁻¹ since the resulting entropy increase (1.4 eu at 1300°K.) improved the overall agreement with the equilibrium data. Based on electron diffraction studies of the monomer-dimer vapor, P. A. Akashin and N. G. Rambidi, Zhur. Neorg. Khim. 4, 718 (1959) have derived the bond distance and angle to be 2.81 Å and 98°. Interpretation of the diffraction data, however, is complicated by the presence of only about 30 mole percent of dimer at the temperature of measurement. Adoption of this dimer structure would reduce the entropy by 0.23 eu, I_B = 60.13 X 10⁻³⁹, and I_C = 105.45 X 10⁻³⁹ g. cm.² Berkowitz structure are I_A = 45.31 X 10⁻³⁹, I_B = 60.13 X 10⁻³⁹, and I_C = 105.45 X 10⁻³⁹ g. cm.²

Cl₂Li₂

Lithium Chloride, Dimeric (LiCl)₂ (Ideal Gas)

Mol. Wt. = 84.794
 ΔH_f^0 298.15 = -143.056 ± 3.0 kcal. mole⁻¹
 $S_{298.15}^0$ = 86.993 cal. deg.⁻¹ mole⁻¹
 Point group = D_{2h}

Vibrational Levels and Multiplicities
 ω , cm.⁻¹ ω_e , cm.⁻¹
 {350} {1}
 {298} {1}
 {395} {1}
 {460} {1}

Bond Lengths and Angles
 Li-Cl distance = 2.23 Å
 Li-Li distance = 2.82 Å
 Cl-Li-Cl angle = 108 ± 4° $\sigma = 4$
 Moment of Inertia $I_{A-B-C} = 6418 \times 10^{-11}$ g.² cm.²

Heat of Formation. A heat of sublimation at 298° of 52.1 kcal. mole⁻¹ was chosen to fit the vapor pressure data and relative concentrations of monomer, dimer and trimer as described in the table for LiCl(g). This value is in reasonable agreement with the value of 53.5 kcal. mole⁻¹ from a 3rd law analysis of the vapor pressure data of An. N. Nesmeyanov and L. A. Sazonov, Zhur. Neorg. Khim. 4, 231 (1960) and the relative concentrations of monomer, dimer, and trimer from the work of R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1956). Also a value of 54.1 kcal. mole⁻¹ was found by T. A. Milne and H. M. Klein, J. Chem. Phys. 33, 1628 (1960), from mass spectrometer studies.

Heat Capacity and Entropy. W. Klemperer and W. G. Norris, J. Chem. Phys. 34, 1071 (1961), observed two bands in the infra-red spectrum and made tentative assignments. The remaining four frequencies were calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), from a reasonable model. The bond lengths and angles were determined from the electron diffraction experiments of S. H. Bauer, T. Ino and R. P. Porter, J. Chem. Phys. 33, 665 (1960).

Dec. 31, 1960; Dec. 31, 1965

S°_{298.15} = 21.422 cal. deg.⁻¹ mole⁻¹
 T_m = 987°K.
 ΔH_f^o 0 = -153.25 ± 0.11 kcal. mole⁻¹
 ΔH_f^o 298.15 = -153.35 ± 0.11 kcal. mole⁻¹
 ΔH_m = 10.30 ± 0.05 kcal. mole⁻¹
 ΔH_g^o 298.15 = 57.5 ± 1.5 kcal. mole⁻¹

Heat of Formation.

The adopted ΔH_f^o 298.15 = -153.35 ± 0.11 kcal. mole⁻¹ is from heat of solution measurements reported by C. H. Shomate and E. H. Huffman, J. Am. Chem. Soc. 65, 1625 (1943). Shomate and Huffmans heat of solution of Mg in 1 M HCl (ΔH = -111.322 ± 0.041 kcal. mole⁻¹), has been substantiated for calibration purposes by S. R. Gunn and B. B. Cunningham, J. Am. Chem. Soc., 79, 1563 (1957) (ΔH = -111.3 kcal. mole⁻¹) and by E. F. Westrum Jr. and L. Eyring, J. Am. Chem. Soc., 74, 2045 (1952) (ΔH = -111.27 kcal. mole⁻¹). Auxiliary heat of dilution and heat of formation data for HCl were taken from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes", NBS-RS-2, Nat'l. Bur. Stds., April 1965 and from D. D. Vagman et al., N.B.S. Technical Note 270-1, Oct. 1965.

Heat Capacity and Entropy.

High temperature heat content data by G. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943) were joined by Shomate correlation with low temperature heat capacity data reported by K. K. Kelley and G. E. Moore, J. Am. Chem. Soc. 65, 1264 (1943). C_p(c) above T_m is a linear extrapolation from 700°K. S°_{298.15} is derived from the low temperature data and is based on S°_{53.6} = 2.006 cal. deg.⁻¹ mole⁻¹.

Melting Data.

ΔH_m = 10.30 ± 0.05 kcal. mole⁻¹ is taken from heat content measurements of Moore loc. cit. T_m = 987°K. is from National Bureau of Standards Circular 500, 1952.

Sublimation Data.

The value of ΔH_g^o 298.15 was derived by 2nd and 3rd law analyses of vapor pressure data. See the MgCl₂(g) table for details.

Cl₂Mg

Magnesium Dichloride (MgCl₂)

(Liquid) Mol. wt. = 95.218

Cl₂Mg

MOL. WT. = 95.218

(LIQUID)

MAGNESIUM DICHLORIDE (MgCl₂)

S_{298.15} = 30.949 cal. deg.⁻¹ mole⁻¹
 T_m = 987°K.
 T_b = [1710]°K.
 ΔH_f⁰ 298.15 = -143.779 kcal. mole⁻¹
 ΔH_m⁰ = 10.50 ± 0.05 kcal. mole⁻¹
 ΔH_v⁰ = [37.34] kcal. mole⁻¹

Heat of Formation.

ΔH_f⁰ 298.15(1) was calculated from ΔH_f⁰ 298.15(c) by adding ΔH_m⁰ and the difference between H_m⁰ - H₂₉₈⁰ for crystal and liquid.

Heat Capacity and Entropy.

A constant C_p(1) = 22.0 cal. deg.⁻¹ mole⁻¹ over the temperature range 1006-1428°K. is from the high temperature heat content data of O. E. Moore, J. Am. Chem. Soc. 65, 1700 (1943). This constant value was assumed to hold from an assumed glass transition of 660°K. to 3000°K. C_p(1) below 860°K. is taken to be that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See MgCl₂(c) table for details.

Vaporization Data.

T_b is calculated as the temperature at which the free energy change of the reaction MgCl₂(l) = MgCl₂(g) approaches zero. The difference between ΔH_f⁰ for MgCl₂(l) and MgCl₂(g) at T_b is ΔH_v⁰.

Cl₂Mg

Point Group D_{2h} $\Delta H_f^\circ = -93.82 \pm 0.5 \text{ kcal/mol}$ $S_{298.15}^\circ = 66.184 \pm 0.5 \text{ gibbs/mol}$ $\Delta H_f^\circ = -93.80 \pm 0.5 \text{ kcal/mol}$

Ground State Quantum Weight = 1

Bond Angle: Cl-Mg-Cl = 180°

Rotational Constant: B₀ = 0.05003 cm⁻¹

σ = 2

Heat of Formation

Analysis of vapor pressure data on MgCl₂ is clouded by conflicting evidence for the amount of dimer in the vapor. Berkowitz and Marquart (1) by mass spectrometer studies found about 21 dimer at 920°K and derived $\Delta H_p^\circ = -39.2 \text{ kcal/mol}$ and $\Delta S_p^\circ = -29.9 \text{ gibbs/mol}$. Schrier and Clark (2) from gas transpiration data calculated about 30% dimer in the saturated vapor at 1300°K, with $\Delta H_p^\circ = -32.0 \text{ kcal/mol}$ and $\Delta S_p^\circ = -18.8 \text{ gibbs/mol}$. Thermodynamic functions for the gaseous monomer adopted here are clearly not compatible with large amounts of dimer and it is assumed for the present that the mass spectrometer results are correct.

Several vapor pressure studies have been published and third law analyses are given below. Berkowitz and Marquart (1) gave a single point while the remaining publications gave only equations but not individual points. Total pressures calculated from the equations were corrected for dimer.

Source	Method	Temperature Range (°K)	$\Delta H_{f298}^\circ (\text{kcal/mol})$
Berkowitz and Marquart (1)	Mass spectrometer	920	58.10
Schrier and Clark (2)	Boiling Point	1208-1413	59.55-59.68
Hildenbrand et al. (3)	Torsion-effusion	802-985	59.55-59.19
Hildenbrand et al. (4)	Torsion-effusion	800-970	59.53-59.38
Fischer et al. (5)	"Hall" method (total vapor pressures)	1136-1435	59.30-59.56

The selected value for ΔH_{f298}° is 59.55 kcal/mol which is combined with ΔH_{f298}° of the crystal to give $\Delta H_{f298}^\circ(\text{g}) = -93.80 \text{ kcal/mol}$.

Heat Capacity and Entropy

White, Mann, and co-workers (6) by matrix infrared spectroscopy determined the molecule to be linear with the asymmetric stretching frequency at 590 cm⁻¹ and the doubly degenerate bending frequency at 88 cm⁻¹. The symmetric stretching frequency was estimated as 273 cm⁻¹. The asymmetric stretching was observed by Buchler and Klemperer (7) at 597 cm⁻¹ and by Randall et al. (8) at 598 cm⁻¹, both by infrared spectroscopy of the vapor at high temperature. Electric deflection experiments by Klemperer and co-workers as summarized by Hayes (9) and the electron diffraction data of Aikshin and Spiridonov (10) agree with the linear structure within their error limits of about 20°. The Mg-Cl bond length was determined as 2.18 Å by Aikshin and Spiridonov (10).

Bond Distance: Cl-Cl = [2.624] Å
Bond Angle: Cl-Cl-Cl = [108.4°]
Product of the Moments of Inertia: I_AI_BI_C = [6.849 X 10⁻¹¹³] g.³ cm.⁶

σ = 4

Heat of Formation.

An analysis is given below of the more extensive measurements relating to the dimer dissociation, (NaCl)₂(g) → 2NaCl(g). The mass spectrometric studies suggest that higher polymeric species may be neglected. Velocity distribution analyses are consistent with this procedure. When reduced to 298.15°K, the observed heats of dissociation of the dimer show a range of more than 7 kcal., reflecting the considerable uncertainty involved in such measurements. A value of ΔH_f⁰ 298 = 48.6 kcal. was selected for the dissociation; combining this with ΔH_f⁰ 298 = 54.9 kcal. mole⁻¹ for sublimation to the monomer leads to ΔH_f⁰ 298 = 61.2 kcal. mole⁻¹ for sublimation to the dimer.

Heat Capacity and Entropy.

The structure and vibrational frequencies are those calculated from an ionic model by J. Berkowitz, J. Chem. Phys. **32**, 1519 (1960); **29**, 1386 (1958). Electron diffraction studies by Akishin and Rabinovich, Z. physik. Chem. (Leipzig) **213**, 111 (1960) gave a similar bond angle (108°) and a slightly shorter bond distance (2.50 Å); however, interpretation of the diffraction pattern was complicated by uncertainty in the monomer-dimer ratio for the vapor. Principal moments of inertia for the Berkowitz structure are I_A = 18.01 X 10⁻³⁹, I_B = 53.31 X 10⁻³⁹ and I_C = 71.32 X 10⁻³⁹ g. cm.².

TUNGSTEN DIOXYCHLORIDE (WO_2Cl_2)

(CRYSTAL)

GFW = 286.7548

$\Delta H_f^\circ = \text{Unknown}$

$S_{298.15}^\circ = [48.0] \text{ gibbs/mol}$

Td = 642°K

Heat of Formation.

S. A. Shchukarev, I. V. Vasil'kova and G. I. Novikov¹ measured calorimetrically the heats of reaction (1) and (2) at 298°K as -67.3 ± 0.2 and $-13.6 \pm 0.11 \text{ kcal/mol}$, respectively. The reactions are given as follows:

- (1) $\text{WO}_2\text{Cl}_2(\text{c}) + 4 \text{ NaOH}(16.3\text{H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(80,000 \text{ H}_2\text{O}) + 2 \text{ NaCl}(40,000 \text{ H}_2\text{O}) + 2 \text{ H}_2\text{O}(1)$
- (2) $\text{H}_2\text{WO}_4(\text{c}) + 2 \text{ NaOH}(16.3 \text{ H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(20,000 \text{ H}_2\text{O}) + 2 \text{ H}_2\text{O}(1)$.

Based on these data and the heats of dilution for $\text{NaOH}(\text{aq})^2$, $\text{NaCl}(\text{aq})^2$ and $\text{Na}_2\text{WO}_4(\text{aq})^3$, we obtain $\Delta H_f^\circ = 53.77 \pm 1.0 \text{ kcal/mol}$ for $\text{WO}_2\text{Cl}_2(\text{c}) + 2 \text{ OH}^-(\infty \text{ H}_2\text{O}) \rightarrow \text{H}_2\text{WO}_4(\text{c}) + 2 \text{ Cl}^-(\infty \text{ H}_2\text{O})$. This leads to $\Delta H_f^\circ(\text{WO}_2\text{Cl}_2, \text{c}) = -186.5 \text{ kcal/mol}$ using $\Delta H_f^\circ(\text{H}_2\text{WO}_4, \text{c}) = -270.5 \pm 0.4 \text{ kcal/mol}$ ⁵.

Heat Capacity and Entropy.

$CP_{300} = 25.0 \text{ gibbs/mol}$ is estimated using Kopp's rule. Heat capacities at higher temperature are estimated from those of $\text{WO}_2(\text{c})$, $\text{WO}_3(\text{c})$, $\text{WOCl}_6(\text{c})$. The entropy, $S_{298}^\circ = 48.0 \text{ eu}$, is calculated from $\Delta S_{298.6}^\circ = 32.27 \pm 1.3 \text{ eu}$ for $\text{WO}_2\text{Cl}_2(\text{c}) \rightarrow \text{WO}_2\text{Cl}_2(\text{g})$. The value of $\Delta S_{298.6}^\circ$ is obtained from the second law analysis of the vapor pressure data given by S. A. Shchukarev and A. V. Suvorov⁴.

Temperature of Decomposition.

Shchukarev and Suvorov⁴ found that $\text{WO}_2\text{Cl}_2(\text{c})$ does not melt but decomposes. The saturated vapor over $\text{WO}_2\text{Cl}_2(\text{c})$ consists mainly of $\text{WOCl}_4(\text{g})$ which will disproportionate to form $\text{WO}_2\text{Cl}_2(\text{g})$ and $\text{WO}_2(\text{g})$. The estimated Td is derived by interpolation to one atmosphere in the total pressures of $\text{WOCl}_4(\text{g})$, $\text{WO}_2\text{Cl}_2(\text{g})$ reported by Shchukarev and Suvorov⁴.

Bond Distance W-Cl = [2.26] Å

Bond Angle Cl-W-Cl = [113°]

Product of the Moments of Inertia: I_AI_BI_C = [1.185 × 10⁻¹¹²] g³ cm⁶

W-O = [1.81] Å

O-W-O = [109.4°]

σ = [2]

Heat of Formation.

The adopted heat of formation, ΔH_f^o (WO₂Cl₂, g) = -160.5 kcal/mol, is obtained from ΔH_f^o = 26.0 kcal/mol for WO₂Cl₂(c) → WO₂Cl₂(g). The latter is calculated by the third law method from the partial pressures of WO₂Cl₂(g) given by S. A. Shchukarev and A. V. Suvorov⁶. Second law analysis gives ΔH_f^o = 24.1 ± 0.8 kcal/mol (ΔH_f^o = 26.0 kcal/mol). These reported partial vapor pressures of WO₂Cl₂(g) were derived by the optical tensimetric method from total pressures over WO₂Cl₂(c) considering the species WOCl₄(g), WO₂Cl₂(g) and WCl₆(g). Since the decomposition of WO₂Cl₂(c) was very complicated, we tentatively assign 6 kcal/mol uncertainty to the adopted heat of formation.

Shchukarev and Suvorov⁶ have also derived a log K_p equation for the disproportionation process,

2 WOCl₄(g) → WO₂Cl₂(g) + WCl₆(g). Third law analysis gives ΔH_f^o = 10.3 kcal/mol for the above process. This leads to ΔH_f^o = -145.7 ± 16 kcal/mol. The second law ΔH_f^o is 11.0 kcal/mol (ΔH_f^o = 10.1 kcal/mol). The drift in the third law analysis is 0.3 eu.

Heat Capacity and Entropy.

The molecular configuration is assumed to be a distorted tetrahedron of C_{2v} symmetry, similar to that of MoO₂Cl₂(g)¹, and CrO₂Cl₂(g)². The bond distances W-O and W-Cl are estimated to be the same as those in WO₃(g) and WCl₆(g), respectively. The bond angles are assumed to be the same as those in MoO₂Cl₂(g)¹. The three principal moments of inertia are I_A = 6.419 × 10⁻³⁸, I_B = 5.342 × 10⁻³⁸ and I_C = 3.397 × 10⁻³⁸ g cm².

The vibrational frequencies, 984 cm⁻¹ and 972 cm⁻¹, were observed in the infrared spectra by C. G. Barraclough and J. Stala³. They tentatively assigned these two as the symmetric and asymmetric W-O stretching frequencies. The rest of the frequencies are estimated by comparison with those observed in the infrared and Raman spectra for CrO₂Cl₂(g)^{4,5}. They are not listed in point group order.

Lead Dichloride (PbCl₂) (Crystal)

Mol. Wt. = 278.12
 $\Delta H_f^{298.15} = -86.20 \pm 0.07$ kcal. mole⁻¹
 $S^{298.15} = 32.5 \pm 0.5$ cal. deg.⁻¹ mole⁻¹
 $\Delta F^{298.15} = 45.59 \pm 0.70$ kcal. mole⁻¹
 $T_m = 768^\circ K$
 $\Delta H_m = 5.70$ kcal. mole⁻¹

Heat of Formation. Recalculated from the data reported by E. J. Salstrom, J. Am. Chem. Soc. 55, 2426 (1933) and A. Wichter, J. Am. Chem. Soc. 54, 2271 (1932).

Heat Capacity, Entropy and Melting Data. C_p (15.3° to 305.5°K.) reported by W. Nernst, Ann. Physik, 35, 395 (1911) and adjusted so that $S^{298.15}$ is equal to the value reported by K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592 (1951). C_p above 298.15°K. obtained from K. K. Kelley, U. S. Bur. Mines Bull. 584 (1950) and joined smoothly to the low temperature heat capacity curve by graphical extrapolation. T_m and ΔH_m obtained from M. Blanc and G. Petit, Compt. rend. 249, 1305 (1959).

Heat of Sublimation. Calculated from vapor pressure data of R. D. Eastman and L. H. Duschak, U. S. Bur. Mines Tech. Paper 225 (1919), C. G. Maier, U. S. Bur. Mines Tech. Paper 360, 28 (1925), H. V. Martenberg and O. Boese, Z. Elektrochem. 28, 384 (1922), and M. Jahn-Held and K. Jellinek, Z. Elektrochem. 43, 491 (1937), which are in good agreement. Vapor pressure was also measured by F. Volmer, Physik. Z. 30, 590 (1929), J. L. Barton and H. Bloom, J. Phys. Chem. 60, 1413 (1956), B. Greiner and K. Jellinek, Z. Physik. Chem. A165, 97 (1933), and K. Mino, M. Sato and M. Yoshiyama, J. Faculty Sci. Hokkaido Imp. Univ. Ser. III, 2, 17 (1940).

Lead Dichloride (PbCl₂) (Liquid)

Mol. Wt. = 278.12

ΔH_f^{298.15} = [-81.49] kcal. mole⁻¹S_{298.15}^o = [39.336] cal. deg.⁻¹ mole⁻¹T_m = 768°KΔH_m^o = 5.70 kcal. mole⁻¹T_b = 1226°KΔH_v^o = 26.81 ± 0.70 kcal. mole⁻¹

Heat of Formation. Calculated from that of the crystal.

Heat Capacity, Entropy and Melting Data. C_p reported by M. Bizouard and P. Pauly, Compt. rend. 252, 51 (1961). T_m and ΔH_m^o obtained from M. Blanc and G. Petit, Compt. rend. 246, 1305 (1959). A glass transition temperature of 520°K. is assumed.

Vaporization Phenomena. T_b and ΔH_v^o calculated from ΔH_f^{298.15} and functions for condensed and gaseous states.

Lead Dichloride (PbCl₂)

(Ideal Gas) Mol. Wt. = 278.12

[70] (1)

[300] (1)

Pb-Cl distance = 2.46 ± 0.02 Å Cl-Pb-Cl angle = 95°

$\sigma = 2$

I_A = 24.223 X 10⁻³⁹ g. cm.² I_B = 39.741 X 10⁻³⁹ g. cm.²

I_C = I_A + I_B = 62.970 X 10⁻³⁹ g. cm.²

Heat of Formation. Calculated from ΔH_f[°] 298.15 for PbCl₂(c) and ΔH_s[°] 298.15.

Heat Capacity and Entropy. Molecular dimensions obtained from L. E. Sutton (ed.), "Tables of Interatomic Distances and Configurations in Molecules and Ions," The Chemical Society, London, 1958. Vibrational frequencies estimated by comparison with the vibrational frequencies for the mercury dihalides.

Bond Distance: Si-Cl = [2.04] Å

Bond Angle: Cl-Si-Cl = [106°]

Product of the Moments of Inertia: $I_A I_B I_C = [5.709 \times 10^{-114}] \text{ g}^3 \text{ cm}^6$ $\sigma = 2$

Heat of Formation

The adopted value is derived from $\Delta H_f^\circ = 78.5 \pm 2 \text{ kcal/mol}$ at 298.15 K for the reaction $\text{Si(c)} + \text{SiCl}_4(\text{g}) \rightarrow 2 \text{SiCl}_2(\text{g})$. JANAF analyses of equilibrium data for this reaction are summarized below. Three sets of data (1, 2, 3) yield average values of ΔH_f° (3rd law) which agree within 0.5 kcal/mol and values of ΔS_f° (2nd law) which are in reasonable agreement with the JANAF functions. Two of the equilibrium studies used flow techniques while the third used a static technique. A median value of ΔH_f° is adopted. Its uncertainty is estimated by assuming that the JANAF entropy for $\text{SiCl}_2(\text{g})$ may be too low by 0.7 gibbs/mol at 1400 K. The adopted value corresponds to ΔH_f° atom = 203.0 kcal/mol and an average bond energy of 101.5 kcal/mol.

Two other flow studies (3, 4) yield large entropy errors, suggesting that there are temperature-dependent errors in K_p . The reported equilibrium constants are reasonable at the lower temperatures but deviate progressively at the higher temperatures. In contrast, the static study of Ichino (5) gave K_p values which differ by a factor of five from the adopted ones. These data yield a consistent entropy but ΔH_f° (3rd law) is lower by 5 kcal/mol.

$\Delta G = \Delta S_f^\circ$ (2nd law) - ΔS_f° (JANAF functions); where equations are used as input, the uncertainties are those given by the original authors.

Heat Capacity and Entropy

The point group is assumed to be the same as that of CF_2 and SiF_2 . The Si-Cl bond length and Cl-Si-Cl bond angle are estimated to be intermediate between those in HSiCl_3 and H_2SiCl_2 . Comparisons with CF_2 , SiF_2 , H_2SiF_2 and H_2SiF_2 confirm that the estimated angle is reasonable. Further confirmation of the structure comes from analysis of isotopic splittings in the infrared spectra of matrix-isolated SiCl_2 . Milligan and Jacox (7) deduced angles of 90 to 120° from alternative assignments for the two stretching vibrations. Observations on argon matrices gave 502 and 513 cm⁻¹ for these vibrations, but it was not possible to decide which is the symmetric mode. Principal moments of inertia are $I_A = 31.25 \times 10^{-39}$, $I_B = 5.035 \times 10^{-39}$, and $I_C = 36.29 \times 10^{-39}$ g cm².

Milligan and Jacox (7) also observed an unstructured absorption in the ultraviolet spectrum. This is the region in which gas-phase emission studies (8) showed features tentatively ascribed to SiCl_2 . Vibrational spacings of about 250 and 540 cm⁻¹ were associated (8) with the ground state; however, this analysis should be reviewed in the light of the matrix spectra. Meanwhile, we estimate that the bending mode should be similar to that in H_2SiCl_2 , probably 190 ± 40 cm⁻¹.

The ground state is assumed to be 3A_1 , as suggested by Hückel-molecular-orbital calculations (9). Singlet excited states

(8, 10) are included near 28000 and 30000 cm⁻¹, but the values are placed in brackets to emphasize the uncertainty in the analysis. Also tentatively adopted is the suggestion by Hastie et al. (10) that the continuous spectrum near 23000 cm⁻¹ is due to a triplet excited state.

Heat of Formation

The heat of formation of $\text{TiCl}_2(\text{c})$ has been measured calorimetrically. The chosen value of ΔH_{298}° is the average of two such determinations. Values of ΔH_{298}° are also calculated from the heats of reaction for the processes (A) $2\text{TiCl}_3(\text{c}) = \text{TiCl}_2(\text{c}) + \text{TiCl}_4(\text{g})$, (B) $3\text{TiCl}_2(\text{c}) = 2\text{TiCl}_3(\text{g}) + \text{Ti}(\text{c})$, and (C) $2\text{TiCl}_2(\text{c}) = \text{TiCl}_4(\text{g}) + \text{Ti}(\text{c})$. These heats of reaction are combined with auxiliary JANAF values for the heats of formation of $\text{TiCl}_3(\text{c})$, $\text{TiCl}_3(\text{g})$, $\text{TiCl}_4(\text{g})$, and $\text{Ti}(\text{c})$. The following table summarizes the data used to calculate ΔH_{298}° .

***Two points rejected due to failure of a statistical test.

Heat Capacity and Entropy

The heat capacity of $\text{TiCl}_2(\text{c})$ has been measured by Kim and Stout (8) over the range 5° to 300°K . They calculated the adopted value of S_{298}° from their measurements based on $S_{298}^\circ = 0.017$ eu. The heat capacity above 300°K is estimated by graphical extrapolation. The large uncertainty on S_{298}° is due to the possibility of sizeable electronic contributions to the heat capacity below 5°K which would account for the rather low value of S_{298}° reported by Kim and Stout (8).

Heat of Sublimation

The heat of sublimation is calculated from the heats of formation of $\text{TiCl}_2(\text{c})$ and $\text{TiCl}_2(\text{g})$. The temperature of sublimation is taken as the point at which $\Delta G^\circ = 0$ for the process $\text{TiCl}_2(\text{c}) = \text{TiCl}_2(\text{g})$. These values are hypothetical since TiCl_2 would be decomposed to $\text{TiCl}_3(\text{g})$ and $\text{TiCl}_4(\text{g})$ below this temperature.

σ = 2

Heat of Formation

Gross and Levi (1) have measured the equilibrium $2\text{TiCl}_3(\text{g}) + \text{Ti}(\text{c}) \rightarrow 3\text{TiCl}_2(\text{g})$ at 1723°K and obtain $\Delta G_{1723}^\circ = 21.7$ kcal/mol from four measurements. This yields $\Delta H_{298}^\circ(\text{TiCl}_2, \text{g}) = -56.7 \pm 3$ kcal/mol. They discuss the measurements of Farber and Darnell (2), on the vapor pressure of $\text{TiCl}_2(\text{c})$, and show that the results are probably in error due to disproportionation of $\text{TiCl}_3(\text{g})$ on condensation. In the work of Skinner and Ruhwain (3) on the reaction $2\text{NaCl}(\text{g}) + \text{Ti}(\text{c}) = 2\text{Na}(\text{g}) + \text{TiCl}_2(\text{g})$, Gross and Levi indicate that the basic assumption, of conversion to TiCl_2 only, is erroneous. In the third law analysis of both these data sets significant drifts are obtained which tends to confirm the above arguments.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $\text{TiCl}_2(\text{c})$ reported by Benzinger and Rundle (4). The vibrational frequencies are estimated from a valence force field model.

The electronic levels are assumed to correspond to the inverted states of $\text{NiCl}_2(\text{g})$ (5). The linear configuration is adopted, since experimental evidence indicates that other transition metal dihalides are linear (6, 7, 8, 9).

TUNGSTEN DICHLORIDE (WCl₂)

(CRYSTAL)

GFV = 254.756

ΔH_f^o = Unknown

ΔH_f^o_{298.15} = -61.5 ± 3 kcal/mol

S_{298.15}^o = [31.2] gibbs/mol

Td = 862°K

Heat of Formation.

The heat of formation, ΔH_f^o (WCl₂, c) = -61.5 ± 3 kcal/mol, is derived from the heat of combustion, ΔH_c^o = -140 ± 3 kcal/mol for WCl₂(c) + 3/2 O₂(g) → WO₃(c) + Cl₂(g), reported by S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kov, A. V. Suvorov, N. V. Andreeva, E. N. Sharupin, and A. K. Baev, Zhur. Khim. 5, 1650 (1960). The value of ΔH_c^o was determined calorimetrically, but no further information about the combustion process was given in the paper.

Heat Capacity and Entropy.

CP₂₉₈ = 6.2 gibbs/g-atom and CP₉₀₀ = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. L. Evans, Metallurgical Thermochemistry, Pergamon Press, New York, 1958. Between 298° and 900°, which is near the decomposition temperature, the heat capacity is obtained by linear interpolation.

The entropy, S₂₉₈^o = 31.2 eu, is estimated by the method of W. M. Latimer, "Oxidation Potentials," 2nd Ed., Prentice-Hall, Inc., New York, 1952. S. A. Shchukarev et al., loc. cit., have estimated ΔS_r^o = -30 eu for W(c) + Cl₂(g) = WCl₂(c) which leads to S₂₉₈^o (WCl₂, c) = 31.1 eu, using JANAF auxiliary data.

Temperature of Decomposition.

The decomposition temperature is obtained by extrapolation to one atmosphere total pressure of a log P versus 1/T fit of the decomposition pressure data reported by S. A. Shchukarev, G. I. Novikov, and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 10, Ser. Fiz. i Khim., No. 2, 78 (1959). Decomposition pressure data for Cl:W ratios less than two suggest that the decomposition reaction is not simple.

Bond Distance: W-Cl = [2.26] Å
Bond Angle: Cl-W-Cl = [180]°
Rotational Constant: B₀ = [0.04655] cm⁻¹
σ = [2]

Heat of Formation.

The value of $\Delta H_{298}^\circ(\text{WCl}_2, g) = -3 \pm 25$ kcal/mol is calculated from the heat of formation of the crystal plus the heat of sublimation, $\Delta H_{298}^\circ = 58.5 \pm 25$ kcal/mol. The latter is estimated from the heats of sublimation of TiCl₂, CrCl₂, MnCl₂, FeCl₂, CoCl₂, NiCl₂ given by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963).

The uncertainty covers the difference between the heats of sublimation among the above compounds and also the possible error in transference from the first row transition metal dichlorides to tungsten dichloride.

S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Beev, Zh. Neorg. Khim. 5, 1650 (1960), have also estimated the heat of sublimation as 102 kcal/mol.

Heat Capacity and Entropy.

The molecular configuration of WCl₂(g) is assumed to be linear. The bond distance is estimated to be the same as that in WCl₆(g). The ground state configuration (Σ), the low lying electronic levels and their quantum weights are assumed to be the same as those for CrCl₂(g), observed by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The vibrational frequencies are calculated from a valence force field model. The stretching force constant, K₁, is estimated to be the same as that of HgCl₂(g), 2.7 millidynes/Å. The bending force constant is assumed to be one hundredth of the stretching force constant. The moment of inertia is I = 6.013 x 10⁻³⁶ g cm².

Sept. 30, 1962; Dec. 31, 1966

GFW = 162.126

(CRYSTAL)

ZIRCONIUM DICHLORIDE (ZrCl_2)

Zirconium Dichloride (ZrCl_2)

(Crystal) GFW = 162.126

$\Delta H_f^\circ = \text{Unknown}$

$\Delta H_{298.15}^\circ = [-103.0 \pm 10] \text{ kcal/mol}$

$\Delta H_m^\circ = [6.4 \pm 3] \text{ kcal/mol}$

$\Delta H_{298.15}^\circ = [58.5 \pm 10] \text{ kcal/mol}$

$S_{298.15}^\circ = [26.3 \pm 3] \text{ gibbs/mol}$

$T_m = [1000]^\circ\text{K}$

Heat of Formation

The value of $\Delta H_{298}^\circ(\text{ZrCl}_2, c) = -103.0 \text{ kcal/mol}$ is calculated from the estimated $\Delta H_{298}^\circ = 58.5 \text{ kcal/mol}$ for $\text{ZrCl}_2(c) + \text{ZrCl}_2(g)$, using $\Delta H_{298}^\circ(\text{ZrCl}_2, g) = -44.5 \text{ kcal/mol}$ (1). The estimated ΔH_{298}° is obtained as an average of the heats of sublimation at 298°K for TiCl_2 , VCl_2 , CrCl_2 , MnCl_2 , FeCl_2 , CoCl_2 , NiCl_2 given by L. Brewer, G. R. Somayajulu and E. Brackett (2).

Heat Capacity and Entropy

The heat capacities of $\text{ZrCl}_2(c)$ are estimated based on the assumption that $C_p(\text{ZrCl}_2, c) = 1/2[C_p(\text{ZrCl}_4, c) + C_p(\text{Zr}, c)]$. The entropy, S_{298}° , is also estimated in a manner similar to that of the heat capacity.

Melting Data

The melting point was estimated to be 1000°K by L. Brewer (3) and the heat of melting was also estimated by A. Glassner (4).

ZIRCONIUM DICHLORIDE (ZrCl₂)

(LIQUID)

GFW = 162.126

$$S^\circ_{298.15} = [29.278] \text{ gibbs/mol}$$

$$\Delta H^\circ_{298.15} = [-98.372] \text{ kcal/mol}$$

$$T_m = [1000]^\circ\text{K}$$

$$\Delta H_m^\circ = [6.4 \pm 3] \text{ kcal/mol}$$

$$T_b = [1565.3]^\circ\text{K}$$

$$\Delta H_v^\circ = [45.0] \text{ kcal/mol}$$

Heat of Formation

The $\Delta H^\circ_{298}(\text{ZrCl}_2, l)$ is calculated from $\Delta H^\circ_{298}(\text{ZrCl}_2, c)$ by adding ΔH_m° and the difference between $H_{1000} - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7.25 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

The melting point was estimated to be 1000°K by L. Brewer (1), and the heat of melting was also estimated by A. Glasner (2).

Vaporization Data

T_b is the temperature at which the Gibbs energy change approaches zero for the process $\text{ZrCl}_2(l) \rightarrow \text{ZrCl}_2(g)$. The difference between ΔH° for $\text{ZrCl}_2(l)$ and $\text{ZrCl}_2(g)$ at T_b is ΔH_v° .

Heat of Formation

Potter (1) investigated mass spectrometrically the gaseous equilibria among ZrCl , ZrCl_2 , ZrCl_3 and ZrCl_4 . Ion intensities were measured 2.5 eV above the ionization threshold. Using the reported equilibrium constants for the reaction $\text{ZrCl}_4(g) + \text{ZrCl}_2(g) \rightleftharpoons 2\text{ZrCl}_3(g)$ in the temperature range 1873-2110°K, second and third law analyses give the heat of reaction at 298°K as -15.8 and +1.7 kcal/mol, respectively. The third law drift is 8.9 ± 3.7 eu. Based on the third law heat of reaction and $\Delta H_f^\circ(\text{ZrCl}_4, g) = -207.77 \text{ kcal/mol}$ (2) and $\Delta H_f^\circ(\text{ZrCl}_3, g) = -125.3 \text{ kcal/mol}$ (3), we obtain $\Delta H_f^\circ(\text{ZrCl}_2, g) = -44.5 \text{ kcal/mol}$ which is adopted in the tabulation.

Farber et al. (4) also studied mass spectrometrically the reaction (a) $\text{Zr}(c) + \text{ZrCl}_4(g) \rightleftharpoons 2\text{ZrCl}_2(g)$ and the reaction (b) $\text{Zr}(c) + \text{ZrCl}_2(g) \rightleftharpoons \text{ZrCl}_3(g)$. They reported second law heats of reaction as $\Delta H_{298}^\circ = 28.8 \pm 1.8 \text{ kcal/mol}$ for reaction (a); and $-141.1 \pm 2.2 \text{ kcal/mol}$ for reaction (b). Third law analysis of the equilibrium constants which were calculated from their ion intensities of run 3 (the only available values) gives $\Delta H_f^\circ(\text{ZrCl}_2, g) = -43.4 \text{ kcal/mol}$. See JANAF $\text{ZrCl}_3(g)$ table (3) for details.

Heat Capacity and Entropy

The molecular configuration is assumed to be linear, since experimental evidence indicates that other transition metal dichlorides are linear (5, 6, 7, 8, 9, 10) even though some fluorides are bent (11). The bond distance is assumed to be the same as that of $\text{ZrCl}_4(g)$. The electronic levels and quantum weights are estimated to be the same as those of $\text{TiCl}_2(g)$ (12).

The vibrational frequencies are calculated from a valence force field model. The stretching force constant is estimated to be 2.5 millidynes/Å and the bending force constant 0.05 millidynes/Å. The moment of inertia is $52.2817 \times 10^{-39} \text{ g cm}^2$.

Bond Distance: Cu-Cl = 2.16 Å

Bond Angle: Cl-Cu-Cl = 150°

Product of the Moments of Inertia: I_AI_BI_C = 2.02847 X 10⁻¹¹¹ g.³ cm.⁶

Heat of Formation.

The heat of sublimation was determined by second and third law analysis of the following vapor pressure data. D. W. Magee, Doctoral Thesis, Ohio State University (1955), measured both vapor pressure by torsion effusion and vapor density in the range 533-644°K. and found only trimer present. The 2nd and 3rd law analyses gave ΔH_f⁰ 298 = 37.37 ± 0.04 and 37.24 ± 0.02 kcal. mole⁻¹ with a drift of -0.25 ± 0.07 cal. deg⁻¹ mole⁻¹. R. A. J. Shelton, Trans. Faraday Soc. 57, 2113 (1961) using Knudsen effusion in the range 547-657°K. obtained ΔH_f⁰ 298 = 40.35 ± 1.4 and 37.42 ± 0.4 kcal. mole⁻¹ with a drift of -4.9 cal. deg⁻¹ mole⁻¹. P. I. Fedorov and M. N. Shakhov, Izv. Vysishikh Uchebn. Zavedenii, Khim. i Khim. Tekhnol. 4, 550 (1961), using transport methods obtained vapor pressures over the liquid from 751-1057°K. Using 2nd and 3rd law analysis these gave ΔH_f⁰ 298 = 38.6 ± 1.0 and 39.27 ± 0.5 kcal. mole⁻¹.

L. Brewer and N. L. Lofgren, J. Am. Chem. Soc. 72, 3038 (1950) obtained equilibrium constants for the reaction 3Cu(c) + 3HCl(g) → Cu₃Cl₃(g) + 1.5 H₂(g). Second and third law analysis of these constants gave ΔH_r⁰ 298 = 3.9 ± 0.6 and 4.39 ± 0.3 kcal. mole⁻¹ which leads to ΔH_f⁰ = -61.8 ± 0.5 kcal. mole⁻¹. This was the value adopted since it is dependent only on HCl(g) and does not involve three times the uncertainty of CuCl(c) as do the sublimation experiments, which yield values in good agreement but of larger uncertainty.

Heat Capacity and Entropy.

The structure of the trimer has been investigated by C-R. Wong and V. Schomaker, J. Phys. Chem. 61, 358 (1957). They conclude that the molecule is planar with D_{3h} symmetry and a Cu-Cl bond length of 2.16 Å. They also state that a very large amplitude of the symmetric in-plane bending appears plausible from the diffraction pattern. The infra-red spectrum has been investigated by W. Klemperer, S. A. Rice and R. S. Berry, J. Am. Chem. Soc. 79, 1810 (1957). They observed one strong absorption with a maximum at 350 cm⁻¹ they attribute this to bond stretching motion of type E'. They also suggest that the broad absorption may involve another mode of approximately equal frequency.

In order to estimate the remaining frequencies we assumed that the other infra-red active E' mode would be close to the observed 350 cm⁻¹ and this was estimated as 300 cm⁻¹. The in-plane bending is the third E' mode and since this has a very large amplitude it was estimated as 60 cm⁻¹. By analogy with other D_{3h} rings the A₂' mode was assumed to be in the same region as the E' stretches and was taken to be 250 cm⁻¹. The 2A₁' stretches were estimated as 100 and 150 cm⁻¹, while the out of plane A₂" was taken as 200 cm⁻¹ and the E" as 80 cm⁻¹. These values gave calculated entropies in excellent agreement with the equilibrium data and thus support the estimates.

The individual moments of inertia were I_A=I_B = 100.472 X 10⁻³⁹ g. cm.², I_C = 200.944 X 10⁻³⁹ g. cm.²

Heat of Formation.

The enthalpy change, $\Delta H_f^\circ 298.15 = -24.49 \pm 0.07 \text{ kcal. mole}^{-1}$, for the reaction $\text{Fe}(\text{ }) + 3(\text{HCl} \cdot 12.751 \text{ H}_2\text{O})(\text{l}) + 1/2(\text{H}_2\text{O}_2 \cdot 12.580 \text{ H}_2\text{O})(\text{l}) = \text{FeCl}_3(\text{c}) + 45.483 \text{ H}_2\text{O}(\text{l})$ was determined by M. P. Koehler and J. P. Coughlin, J. Phys. Chem. **63**, 605 (1959). This leads to $\Delta H_f^\circ 298.15 = -95.46 \pm 0.20 \text{ kcal. mole}^{-1}$ for $\text{FeCl}_3(\text{c})$, using $\Delta H_f^\circ 298.15 = -38.9 \pm 0.05$ and $-45.68 \pm 0.01 \text{ kcal. mole}^{-1}$ for hydrochloric acid and hydrogen peroxide solution, respectively, obtained from F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine and I. Jaffe, National Bureau of Standards Circular 500, 1952. From $\Delta H_f^\circ 298.15 = -38.0 \pm 0.2 \text{ kcal. mole}^{-1}$ for the reaction $\text{FeCl}_3(\text{c}) = \text{Fe}^{+++}(\text{aq.})$ reported by J. C. M. Li and N. V. Gregory, J. Am. Chem. Soc. **74**, 4670 (1952), the value of $\Delta H_f^\circ 298.15$ (FeCl_3, c) was calculated as $-95.26 \pm 0.2 \text{ kcal. mole}^{-1}$. The former $\Delta H_f^\circ 298.15$ value is adopted.

The equilibrium pressures of the reaction $2 \text{FeCl}_2(\text{c}) + \text{Cl}_2(\text{g}) = 2\text{FeCl}_3(\text{c})$, in the temperature range of 435.7-482.2°K., were measured by H. Schäfer and E. Oehler, Z. anorg. allgem. Chem. **271**, 206 (1953). Using the reported partial pressures for $\text{Cl}_2(\text{g})$, the enthalpy change ($\Delta H_f^\circ 298.15$) of the reaction was evaluated as -27.49 ± 0.44 and $-27.21 \text{ kcal. mole}^{-1}$ by the second and third law methods, respectively. Based on the third law value for $\Delta H_f^\circ 298.15$, the value of $\Delta H_f^\circ 298.15$ (FeCl_3, c) was derived to be $-95.36 \pm 0.12 \text{ kcal. mole}^{-1}$ which is in good agreement with the adopted value.

Heat Capacity and Entropy.

The low temperature (51-298.15°K.) heat capacities and high temperature (339.6-560.9°K.) heat content of $\text{FeCl}_3(\text{c})$ were determined by S. S. Todd and J. P. Coughlin, J. Am. Chem. Soc. **73**, 4184 (1951). The low temperature C_p and the derived high temperature C_p were plotted. The two C_p curves were joined smoothly at 298°K. The C_p values above 560.9°K. were obtained by graphical extrapolation. The value of $S_{298.15}^\circ$ was derived from the low temperature data reported by S. S. Todd and J. P. Coughlin, loc. cit., using $S_{51}^\circ = 6.29 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$. The value of $S_{298.15}^\circ$ was selected to make the second and third law values of ΔH_f° , derived from the equilibrium data reported by H. Schäfer and E. Oehler, loc. cit., in good agreement. The difference in S_{51}° between the selected value, 6.29, and the reported value, 4.50 cal. deg. $^{-1} \text{ mole}^{-1}$, by S. S. Todd and J. P. Coughlin, loc. cit., is assumed to be the magnetic entropy remaining at 51°K. which was unaccounted for in the report.

Melting Data.

T_m and ΔH_m° were obtained from S. S. Todd and J. P. Coughlin, loc. cit.

Heat of Sublimation.

The difference between $\Delta H_f^\circ 298.15$ for $\text{Fe}_2\text{O}_3(\text{g})$ and $2\text{FeCl}_3(\text{c})$ is the heat of sublimation at 298.15°K. The former is obtained by the second and third law analyses of related equilibrium data. See $\text{Fe}_2\text{O}_3(\text{g})$ table for details.

IRON TRICHLORIDE (FeCl₃)

(LIQUID)

MOL. WT. = 162.206

S_{298.15} = 47.955 cal. deg.⁻¹ mole⁻¹
 ΔH_f^o 298.15 = -86.713 kcal. mole⁻¹
 ΔH_m^o = 10.30 kcal. mole⁻¹
 ΔH_v^o (to dimer) = 10.46 kcal. mole⁻¹
 T_m = 577°K.
 T_b = 805°K.

Heat of Formation.

The value of ΔH_f^o 298.15 (FeCl₃, l) was obtained from ΔH_f^o 298.15 (FeCl₃, c) by adding ΔH_m^o and the difference between H_m^o - H_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity for FeCl₃(l) was taken from S. S. Todd and J. P. Coughlin, J. Am. Chem. Soc. 73, 4184 (1951) and assumed as constant between 298.15° and 1500°K. The entropy (S_{298.15}) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and ΔH_m^o were reported by S. S. Todd and J. P. Coughlin, loc. cit.

Vaporization Data.

The boiling point (T_b) is determined as the temperature at which the free energy change (ΔG_p^o) of the reaction 2FeCl₃(l) = Fe₂Cl₆(g) approaches zero. The corresponding enthalpy change at T_b is the heat of vaporization (ΔH_v^o).

IRON TRICHLORIDE (FeCl₃)

(IDEAL GAS)

MOL. WT. = 162.206

Point Group [D_{3h}]ΔH_f⁰ = -80.5 ± 1.2 kcal. mole⁻¹S_{298.15} = [82.243] cal. deg⁻¹ mole⁻¹ΔH_f⁰ 298.15 = -80.5 ± 1.2 kcal. mole⁻¹

Ground State Quantum Weight = [6]

Vibrational Frequencies and Degeneracies

 ω , cm⁻¹
 [350] (1)
 [180] (1)
 [310] (2)
 [130] (2)

Bond Distance: Fe-Cl = [2.17] Å

Bond Angle: Cl-Fe-Cl = [120]°

Product of the Moments of Inertia: I_AI_BI_C = [1.43769 × 10⁻¹¹²] g.³ cm.⁶σ⁻ = [6]

Heat of Formation.

The equilibrium pressures for the reaction Fe₂O₃(g) = 2FeCl₃(g) were determined by Kangro and Bernstorff¹ and Schüfer², respectively. Using their vapor pressure data the corresponding values of ΔH_f⁰ 298.15 for that reaction were evaluated by both the second and third law methods. Based on the third law values for ΔH_f⁰ 298.15, the heats of formation (ΔH_f⁰ 298.15) for FeCl₃(g) were derived. The results obtained are presented as follows.

Investigator	Temperature, °K.	Second Law Value	Third Law Value	ΔH _f ⁰ 298.15, kcal. mole ⁻¹
Kangro and Bernstorff ¹	760.2-1044.2	34.99 ± 0.44	35.75	-60.34 ± 0.30
Schüfer ²	675.2-1073.2	34.81 ± 0.02	34.93	-60.74 ± 0.20

¹ W. Kangro and H. Bernstorff, Z. anorg. allgem. Chem. **283**, 316 (1950).

² H. Schüfer, Z. anorg. allgem. Chem. **259**, 53 (1949).

 The adopted value of ΔH_f⁰ 298.15(FeCl₃ g) is -80.5 ± 1.2 kcal. mole⁻¹.

Heat Capacity and Entropy.

The molecular structure was assumed to be the same as that of AlCl₃(g) due to the similarities in structure between Fe₂O₃(g) and Al₂O₃(g). The Fe-Cl bond distance was estimated by comparison with those for Fe₂Cl₆(g) reported by E. Z. Zasorin, N. O. Rambidi and P. A. Akishin, Zh. Strukt. Khim., **4**, 910 (1963) and O. Hassel and H. Viervoll, Acta Chem. Scand., **1**, 149 (1947). Both the ground state quantum weight and vibrational frequencies were estimated so that the second and third law values of ΔH_f⁰ 298.15, derived from the vapor pressure data, for the reaction Fe₂O₃(g) = 2FeCl₃(g) are in reasonable agreement. The three principal moments of inertia are: I_AI_BI_C = 4.15794 × 10⁻³⁸ and I_C = 8.31588 × 10⁻³⁸ g. cm.²

Cl₃HSi

Trichlorosilane (HSiCl₃)

(Ideal Gas)

Mol. Wt. = 135.469

ΔH_f^o 298.15 = -119.6 kcal. mole⁻¹

S_{298.15} = 74.924 cal. deg.⁻¹ mole⁻¹

Point Group C_{3v}

Ground State Multiplicity = 1

Vibrational Frequencies and Degeneracies

, cm.⁻¹

2274 (1) 810 (2)

497 (1) 600 (2)

250 (1) 179 (2)

Si-H dist. = 1.48 all angles = [109° 28']

Si-Cl dist. = 2.02 = 3

Product of Moments of Inertia: I_AI_BI_C = 75.642 X 10⁻¹¹ g.³ cm.⁶

Heat of Formation. ΔH_f^o 298.15 was calculated from heats of reaction reported by E. Wolf, Z. Anorg. u. Allgem. Chem. 313, 228 (1961) for the equation

SiHCl₃(g) + 5NaOH(c) = Na₂SiO₃(c) + 3NaCl(c) + 2H₂O(l)

Heat Capacity and Entropy. Molecular constants were found in Janz and Mikawa, Bull. Chem. Soc. Japan 34, 1495 (1961). Vibrational frequencies can also be found in Henderson and Scheffer, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data," January, 1960.

Lithium Chloride, Trimeric (LiCl)₃ (Ideal Gas)

Mol. Wt. = 127.19
ΔH_f^o 298.15 = -240.134 + 5 kcal. mole⁻¹
S_{298.15}^o = 80.223 cal. deg.⁻¹ mole⁻¹
Point Group = D_{3h}

Vibrational Levels and Multiplicities
 ω_e , cm.⁻¹
 $\left[\begin{smallmatrix} 650 \\ 550 \end{smallmatrix} \right] \left\{ \begin{smallmatrix} 8 \\ 6 \end{smallmatrix} \right\}$

Bond distances and angles Li-Cl distance = [2.2] Å
LiClLi angle [120°]
Plane cyclic structure σ = 8

Moment of Inertia I_AI_BI_C = 2.675 × 10⁻¹¹² g.³ cm.⁶

Heat of Formation. The heat of sublimation at 298° was chosen so as to give the correct ratio of monomer, dimer and trimer at 870°K. The value used was 52.6 kcal. mole⁻¹, which compares very well with the value 53.6 kcal. mole⁻¹ obtained from a third law analysis of the data of An. N. Nemesyov and L. A. Sazonov, Zhur. Neorg. Khim. 4, 231 (1960) in conjunction with the relative concentrations of monomer, dimer, and trimer at 870°K from the work of R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1950).

Heat Capacity and Entropy. The postulated structure, bond lengths and frequencies were all taken from D. L. Hildenbrand, A. M. Saul P. R. Basford, S. E. Stephenson, L. Larson and A. Uyehara, Aero-nutronics Renth Quarterly Report on Contract NORD 17960 Report C-898 (1960).

581 (2)	267 (2)	193 (2)

P-O distance = $1.99 \pm 0.02 \text{ \AA}$
 $I_A = 422.3 \times 10^{-40} \text{ g. cm.}^2$
 $I_B = 412.2 \times 10^{-40} \text{ g. cm.}^2$
 $I_C = 576.7 \times 10^{-40} \text{ g. cm.}^2$
 $\sigma = 3$

Heat of Formation.

The $\Delta H_f^\circ 298.15$ for $\text{POCl}_3(\text{g})$ was derived from the $\Delta H_f^\circ 298.15$ of $\text{POCl}_3(\text{l})$ and the $\Delta H_v^\circ 298.15$ of the $\text{POCl}_3(\text{l})$ was calculated from the heat of hydrolysis observed by T. Charnley and H. A. Skinner, J. Chem. Soc., 450, (1953) for the reaction:

The auxiliary thermochemical data, on the heats of formation of water and aqueous solutions of HCl and of H_3PO_4 , were taken from the National Bureau of Standards, "Selected Values of Chemical Thermodynamic Properties," Circular 500, and were adjusted for consistency with JANAF tables. The heat of vaporization was measured and corrected to 298.15°K by J. B. Ott and W. P. Glaueque, J. Am. Chem. Soc., 82, 1308 (1960). A correction was made for the change in phosphorus reference state [white (α) \rightarrow red (γ)].

Heat Capacity and Entropy.

The molecular constants are from the microwave spectral data of Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys., 20, 164 (1952). In order to determine the structure Williams et al. (loc. cit.) assumed the P-Cl distance equal to 1.99 \AA . This was the smallest value allowed ($2.02 \pm 0.03 \text{ \AA}$) by the electron diffraction work of L. O. Brockway and J. Y. Beach, J. Am. Chem. Soc., 60, 1836 (1938).

Ott and Glaueque (loc. cit.) have given the moments of inertia obtained from a weighted average of the isotopic species. I_A , I_B due to isotopic loss of symmetry. The $S_{298.15}^\circ$ calculated from calorimetric data by Ott and Glaueque (loc. cit.) was $77.75 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ and the $S_{298.15}^\circ$ calculated from the spectral data was $77.77 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Point Group C_{3v}
S_{298.15} = 74.47 ± 0.10 gibbs/mol
Ground State Quantum Weight = 1
ΔH_f⁰ = -84.5 ± 1.3 kcal/mol
ΔH_f^{298.15} = -64.8 ± 1.3 kcal/mol

Dec. 31, 1960, Sept. 30, 1962, June 30, 1970

Neale and Williams (1) measured the heat of hydrolysis of liquid phosphorus trichloride and reported a ΔH_p = -87.5 ± 0.3 kcal/mol for the following reaction:
PCl₃(l) + (X₂ + 3) H₂O + H₃PO₃(aq) + 3 HCl(aq)
with X₂ in range 4500 to 7500. Combining this result with heat of formation data for aqueous H₃PO₃, -229.4 kcal/mol (2, 5, 16), H₂O (2), and aqueous HCl (2) we derive ΔH_f⁰(PCl₃, l) = -76.7 kcal/mol. Chamley and Skinner (3) made an independent investigation of the hydrolysis of liquid phosphorus trichloride and obtained enthalpy data in very good agreement with Neale and Williams' results. Their results lead to ΔH_f⁰(PCl₃, l) = -76.5 kcal/mol when combined with heat of formation data (2, 5, 16).
Neale and Williams (4) also investigated the hydrolysis of liquid phosphorus trichloride in aqueous bromine solution with the formation of phosphoric acid rather than phosphorous acid which results when hydrolysis occurs in water. They reported a ΔH_p = -137.9 kcal/mol for the following reaction:
PCl₃(l) + Br₂(aq) + (X₂ + 4) H₂O + H₃PO₄(aq) + 3 HBr(aq) + 2 HBr(aq)
with X₂ in range 3500 to 8300. Combining this result with the following heat of formation data:
ΔH_f⁰(H₃PO₄·1/2 H₂O) = -308.4 ± 0.5 kcal/mol (5)
ΔH_f⁰(Br₂(aq)) = -0.2 kcal/mol (6)
HCl(aq) and HBr(aq) (2)
along with dilution data for H₃PO₄(aq) (2), we derive ΔH_f⁰(PCl₃, l) = -77.0 kcal/mol.

The heat of formation from white phosphorus of gaseous PCl₃, ΔH_f⁰(PCl₃, g) = -89.0 ± 1.1 kcal/mol, is calculated from the heat of formation of the liquid, ΔH_f⁰(PCl₃, l) = -76.7 ± 1.0 kcal/mol, an average value of the three results given above, and the heat of vaporization of PCl₃. The heat of vaporization of the liquid, ΔH_v⁰ = 7.7 ± 0.1 kcal/mol, is determined from a second law analysis of the combined vapor pressure data of Misel von and Saryakov (7) and Regnault (8). The smoothed vapor pressure data of Regnault as reported by Stull (9) were used. Converting to the P_{red}, V standard state with a ΔH_{trans} = 4.2 ± 0.2 kcal/mol (10), we derive ΔH_f⁰(PCl₃, g) = -84.8 ± 1.3 kcal/mol.
An independent value for the heat of formation can be obtained from the work of Duss and Mykytiuk (12) on the reaction
1.5CaF₂ + PCl₃(g) + 1.5CaCl₂ + PF₃(g). The authors report ΔH₃₀ = -2.97 kcal. From a reexamination of their technique we believe that this heat evolution is likely to be too small, perhaps by 100%. The analytical results indicate that the reaction is 99% complete or better; thus, we can use this with JANAF entropies to calculate ΔH₂₉₈⁰ = -3.55 kcal. Finch et al. (13) have reported ΔH_f⁰(CaF₂, o) - ΔH_f⁰(CaCl₂, c) = -100.87 ± 0.02 kcal/mol; thus, we obtain ΔH_f⁰(PCl₃, g) = -70.1 ± 2.0 kcal/mol from ΔH₂₉₈⁰(PF₃, g) = -224.9 ± 0.9 kcal/mol. This value is not adopted because of the lack of calorimeter calibration, but it offers an attractive possibility for further study.

Heat Capacity and Entropy
The molecular structure and bond length given above for PCl₃ are from the electron diffraction studies of Hedberg and Iwamide (11). The adopted values are in good agreement within experimental error with the following structural data reported by Klatuk and Townes (12) from microwave studies: P-Cl = 2.043 ± 0.003 Å, the angle Cl-P-Cl = 100° ± 20'. The vibrational frequencies are from the recent infrared and Raman studies of Frankiss and Miller (13) and are in excellent agreement with those of Miller et al. (14) and Davis and Oetjen (15). Individual moments of inertia calculated from the electron diffraction data are: I_A = I_B = 32.393 × 10⁻³⁹ g cm², and I_C = 57.673 × 10⁻³⁹ g cm².

Dec. 31, 1960, Sept. 30, 1962

Thiophosphoryl Chloride (PCl₃)
(Ideal Gas)
Mol. Wt. = 169.412
ΔH°_f 298.15 = [-86.8] kcal. mole⁻¹
S°_{298.15} = 80.60 cal. deg⁻¹ mole⁻¹
Point Group C_{3v}

Vibrational Frequencies and Degeneracies

ω _v , cm ⁻¹	ω _v , cm ⁻¹	ω _v , cm ⁻¹
169 (2)	[247] (2)	247 (1)
431 (1)	540 (2)	751 (1)

Bond distance P-S = 1.65 ± 0.02 Å P-Cl = 2.02 ± 0.01 Å σ = 3
Cl-P-Cl angle = 100.5° ± 1° I_AI_BI_C = 2.0690 × 10⁻¹¹² g. cm.⁶
Heat of Formation. ΔH°_f 298 was estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corporation, Alexandria, Virginia, "Survey of Thermochemical Data," January 1960. Henderson and Scheffee (loc. cit.) use white(α) phosphorus as a reference state. Their estimated ΔH°_f 298 was adjusted to the Red (V) phosphorus reference state [see White(α) phosphorus sheet.]

Heat Capacity and Entropy. J. S. Ziomek and E. A. Piotrowski, J. Chem. Phys. 34, 1087 (1961) have chosen the most probable values for the wave numbers from the infrared spectral data of G. Cilento, D. A. Ramsey, and R. N. Jones, J. Am. Chem. Soc. 71, 2753 (1949), and the Raman spectral data of A. Simon and G. Schulze, Naturwissenschaften 25, 669 (1937); V. N. Matthe, Nature 139, 469 (1935); H. Gerding and R. Westrick, Rec. trav. chim. 61, 842 (1942); and M. Delvaux and F. Francos, Compt. Rend. 220, 817 (1945). Ziomek and Piotrowski (loc. cit.) found their normal coordinate treatments gave the listed wave numbers as fundamentals and lent support for the 247 cm⁻¹ band missing from the Raman spectral data. The structure, (bond distances and angles) was determined from microwave data by Q. Williams, J. Sheridan, and W. Gordy, J. Chem. Phys. 20, 164 (1952).

Vibrational Frequencies and Degeneracies

$\frac{\omega}{\text{cm}^{-1}}$	$\frac{g}{\text{cm}^{-1}}$
470 (1)	582 (2)
[240] (1)	[175] (2)

Bond Distance: Si-Cl = (2.02 ± 0.02) ÅBond Angle: Cl-Si-Cl = 110.9° Product of the Moments of Inertia: $I_A I_B I_C = [7.5469 \times 10^{-113}] \text{ g cm}^6$ $\sigma = 3$

Heat of Formation

The adopted value is derived from an average bond energy of $\Delta H_{\text{atom}}^\circ/3 = 96 \pm 3$ kcal/mol. This value is estimated by comparison of average bond energies for SiH_n where $M = \text{C or Si}$, $X = \text{F or Cl}$, and $n = 2, 3$ or 4 . These comparisons suggest that the average bond energy for SiCl_3 should be bracketed by those for SiCl_4 and SiCl_2 , i.e. 94.3 and 101.5 kcal/mol, respectively. Alternative estimates from linear plots of $\Delta H_f^\circ(\text{SiCl}_n)$ versus ΔH_f° for SiF_n , CCl_n , and CF_n yield -98, -96, and -86 kcal/mol for ΔH_f° of SiCl_3 at 298.15°K. These agree with the adopted value of -96 \pm 10 kcal/mol, which corresponds to $\Delta H_{\text{atom}}^\circ = 288 \pm 10$ kcal/mol.

Kerr et al. (1) reported relative rates for several reactions of SiCl_3 , but the authors state that no absolute activation energies are known for reactions of this radical. This precludes derivation of thermochemical values from the kinetic studies. Recently, however, Vurzel et al. (4) reported studies of the decomposition of SiCl_4 by adiabatic compression. Rate constants, as reported in Chemical Abstracts, led to an activation energy of 86 ± 5 kcal/mol for $\text{SiCl}_4 \rightarrow \text{SiCl}_3 + \text{Cl}$. The activation energy for recombination should be very close to zero, so $\Delta H_r = 86 \pm 5$ compared with the adopted result of 86 ± 10 at room temperature. Steele et al. (2) derived an average value of $D(\text{Cl}_3\text{Si-H}) = 93 \pm 4$ kcal/mol from an interpretation of electron impact studies on several molecules. Using $\Delta H_f^\circ(\text{Cl}_3\text{SiH}, g) = -122.6$ kcal/mol (3), we calculate $\Delta H_f^\circ(\text{SiCl}_3, g) = -82$ kcal/mol and estimate the uncertainty as about 10 kcal/mol.

Heat Capacity and Entropy

Jacob and Milligan (5) studied the formation of SiCl_3 by photolysis of HSiCl_3 trapped in matrices of argon, nitrogen and CO. The two stretching fundamentals were assigned from the infrared spectra. Isotopic splittings were found to be consistent with an angle of $72 \pm 5^\circ$ between the threefold axis and each of the Si-Cl bonds. This yields a bond angle of 110.9° which is similar to that of HSiCl_3 . Non-planarity of SiCl_3 is consistent with the electron-spin-resonance studies of Roncin (6).

We adopt the results of Jacob (5) and estimate the bond length and two bending vibrations by analogy with HSiCl_3 . Similar analogies are reliable for SiF_3 and CF_3 . The ground state quantum weight is taken as two, but excited electronic levels are neglected. Jacob (5) observed unstructured absorptions corresponding to excitation energies of 30000-34500 cm^{-1} and 41000-46000 cm^{-1} . Principal moments of inertia are $I_A = 65.18 \times 10^{-39}$ and $I_B = I_C = 34.03 \times 10^{-39} \text{ g cm}^2$.

TITANIUM TRICHLORIDE (TiCl₃)

(CRYSTAL)

GFW = 154.259

ΔH_f^o = -173.1 ± 1.0 kcal/mol
 ΔH_f^o_{298.15} = -172.5 ± 1.0 kcal/mol
 ΔH_f^o = 0 kcal/mol
 ΔH_s^o = [39.71] kcal/mol

S_{298.15} = 33.4 ± 0.3 gibbs/mol

T_m = 220.1°K

T_s = [1104.1]°K

Heat of Formation

The heat of formation, ΔH_f^o₂₉₈, of TiCl₃(c) has been measured by several investigators. The results of these measurements are as follows.

Investigators

Investigator	Method	ΔH _f ^o , Kcal/mol
Schaffer et al. (1954) (1)	Calorimetric, TiCl ₄ + Hg = TiCl ₃ + 1/2Hg ₂ Cl ₂	-171.9, -172.4
Clifton and MacWood (1956) (2)	Solution calorimetric	-172.4
Johnson et al. (1956) (3)	Calorimetric, TiCl ₄ (l) + Hl(g) = TiCl ₃ (c) + HCl(g) + 1/2I ₂	-172.5
Krievie et al. (1956) (4)	Solution calorimetric	-171.3
Krievie and Mason (1956) (5)	Equilibrium, TiCl ₃ (c) + HCl(g) = TiCl ₄ (g) + 1/2H ₂ (g)	-172.9
Altman et al. (1956) (6)	Equilibrium, 2TiCl ₃ (c) + 3TiCl ₄ (g) = 4TiCl ₃ (c)	-189.4, -171.0
Head (1960) (7)	Equilibrium, 2TiCl ₄ (2) + H ₂ (g) = 2TiCl ₃ (c) + 2HCl(g)	-172.3
	TiCl ₄ (l) + Hg(l) = 1/2Hg ₂ Cl ₂ (c) + TiCl ₃ (c)	
	TiCl ₄ (l) + Ag(c) = AgCl(c) + TiCl ₃ (c)	

The chosen value of -172.5 ± 1.0 kcal/mol is that reported by Johnson et al. (3).

Heat Capacity and Entropy

The heat capacity and entropy of TiCl₃(c) has been measured over the temperature range 54° to 1000°K by King et al. (8). The value of S₂₉₈^o is calculated from these data based on S₂₁^o = 4.29 eu.

Transition Data

A second order transition at 220.1°K was observed by King et al. (8). The heat capacity at this temperature is in excess of 146.8 gibbs/mol. King et al. measured the value of H₂₄₀^o - H₂₀₀^o as 1.213 kcal/mol.

Heat of Sublimation

The heat of sublimation is calculated from the heats of formation of TiCl₃(c) and TiCl₃(g) at the sublimation temperature. The sublimation temperature is taken as the point at which ΔGr = 0 for the process TiCl₃(c) = TiCl₃(g).

Heat of Formation

The heat of formation of TiCl₃(g) is calculated from the heats of reaction for the processes, (A) 3TiCl₂(g) + Ti(c) = 4TiCl₃(g) and (B) TiCl₂(c) = TiCl₃(g), combined with auxiliary JANAF heats of formation for TiCl₂(g), TiCl₂(c) and Ti(c). Equilibrium measurements of reaction (A) have been reported by Gross and Levi (1). Vapor pressure measurements for reaction (B) have been reported by Sanderson and Macdonald (2) and by Farber and Darnell (3). Second and third law analyses of these data yield the following results.

Source	Reaction	No. Points	Range, °K	ΔH _f °, kcal/mol	Second Law	Third Law	Drift, eu	ΔH _f °298*
Gross and Levi (1)	A	3	1223			31.6 ± 2.0		-126.5
Sanderson and Macdonald (2)	B	9**	628-823		42.8 ± 1.1	42.8	-0.1 ± 1.5	-129.3
Farber and Darnell	B	8	636-732		45.3 ± 2.1	45.8	0.8 ± 3.1	-126.2

*Calculation based on third law ΔH_f°298.

**One point rejected due to failure of statistical test.

The chosen value of ΔH_f°298 is -128.9 kcal/mol. This value is the average of the first two determinations.

Heat Capacity and Entropy

The interatomic distance is estimated from that of the solid, given as 2.46 Å by Matte et al. (4), and from comparisons of bond distances of crystal and gas phase tetrahalides of titanium. The pyramidal bond angle is estimated assuming TiCl₃(g) similar to the group V trihalides. The principal moments of inertia are I_A = 4.29 × 10⁻³⁸ g cm² and I_C = 7.26 × 10⁻³⁸ g cm². The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti³⁺ (5).

ZIRCONIUM TRICHLORIDE (ZrCl_3)

Zirconium Trichloride (ZrCl_3)

GFW = 197.579

(Crystal)

$\Delta H_f^\circ = \text{Unknown}$

$\Delta H_f^\circ_{298.15} = [-170.7 \pm 15] \text{ kcal/mol}$

$\Delta H_f^\circ_{298.15} = [45.4] \text{ kcal/mol}$

$S^\circ_{298.15} = [34.8 \pm 3] \text{ gibbs/mol}$

$T_s = [1045.9]^\circ\text{K}$

Heat of Formation

Turnbull and Watts (1) determined the equilibrium pressures for the disproportionation of $\text{ZrCl}_3(\text{c})$ in the temperature range from 613°K to 723°K by a modified dew point technique. Third law and second law analyses of their vapor pressure-temperature equation give the same heat of reaction $\Delta H_{298}^\circ = 30.7 \text{ kcal/mol}$ for $2\text{ZrCl}_3(\text{c}) \rightarrow \text{ZrCl}_2(\text{c}) + \text{ZrCl}_4(\text{g})$. The adopted value, $\Delta H_f^\circ(\text{ZrCl}_3, \text{c}) = -170.7 \text{ kcal/mol}$, is calculated from the heat of reaction at 298°K, and $\Delta H_f^\circ(\text{ZrCl}_4, \text{g}) = -207.77 \text{ kcal/mol}$ (2) and $\Delta H_{298}^\circ(\text{ZrCl}_2, \text{c}) = -103 \text{ kcal/mol}$ (3). The assigned uncertainty, $\pm 15 \text{ kcal/mol}$ is mainly due to the uncertainty in the heat of formation of $\text{ZrCl}_2(\text{c})$, and also the dew point technique used.

Heat Capacity and Entropy

The heat capacities of $\text{ZrCl}_3(\text{c})$ are estimated from the Cp values of $\text{ZrCl}_4(\text{c})$ by deduction of one Cl atom Cp contributions which are calculated as $1/4(\text{Cp}(\text{ZrCl}_4, \text{c}) - \text{Cp}(\text{Zr}, \text{c}))$. The S_{298}° is calculated as 34.85 eu based on the assumption that $S_{298}^\circ(\text{ZrCl}_3, \text{c}) = S_{298}^\circ(\text{ZrCl}_4, \text{c}) - 1/4(S_{298}^\circ(\text{ZrCl}_4, \text{c}) - S_{298}^\circ(\text{Zr}, \text{c}))$.

Heat of Sublimation

The heat of sublimation is calculated from the difference in the heats of formation of gas and crystal at 298°K. The sublimation temperature is taken as the point at which $\Delta G^\circ = 0$ for $\text{ZrCl}_3(\text{c}) = \text{ZrCl}_3(\text{g})$.

Heat of Formation

Potter (1) investigated mass spectrometrically the equilibrium $\text{CaCl}_2(\text{g}) + \text{ZrCl}_4(\text{g}) \rightleftharpoons \text{ZrCl}_2(\text{g}) + \text{ZrCl}_3(\text{g})$ in the temperature range 1163-1577°K. Ion intensities were measured 2.5 eV above threshold and they were used in the calculation of equilibrium constants. Using the reported equilibrium constants, the heats of reaction at 298°K are evaluated by the third law and second law methods as -3.69 and -16.67 kcal/mol, respectively. The third law drift is 9.31 ± 1.25 eu. Using the third law $\Delta H_f^\circ = -3.69$ kcal/mol, $\Delta H_f^\circ(\text{ZrCl}_4, \text{g}) = -207.77$ kcal/mol (2), $\Delta H_f^\circ(\text{CaCl}_2, \text{g}) = -28.8$ kcal/mol (3) and $\Delta H_f^\circ(\text{ZrCl}_2, \text{g}) = -115.0$ kcal/mol (4), we obtain $\Delta H_f^\circ(\text{ZrCl}_3, \text{g}) = -125.3$ kcal/mol, which is adopted in the tabulation.

Farber et al. (5) also studied mass spectrometrically the reaction $\text{Zr}(\text{c}) + 3\text{ZrCl}_2(\text{g}) \rightleftharpoons 4\text{ZrCl}_3(\text{g})$ in the temperature range from 1579°K to 1729°K. They reported a second law heat of reaction as $\Delta H_f^\circ = 59.2 \pm 1.6$ kcal/mol. Since the attainment of equilibrium was questionable in their studies, the heat of reaction obtained from the third law method is generally more reliable. Using their reported ion intensities of run 3 (temperature range from 1667°K to 1898°K, five points), we have calculated the equilibrium constants $K_1 = (I_{\text{ZrCl}_3})^2 / (I_{\text{ZrCl}_2})^3$ for reaction (1) $\text{ZrCl}_3(\text{g}) + \text{ZrCl}_3(\text{g}) \rightleftharpoons 2\text{ZrCl}_2(\text{g})$, and $K_2 = (I_{\text{ZrCl}_3})^2 / (I_{\text{ZrCl}_4})^2$ for reaction (2) $\text{ZrCl}_3(\text{g}) + \text{ZrCl}_4(\text{g}) \rightleftharpoons 2\text{ZrCl}_2(\text{g})$. Third law analyses of the equilibrium constants give $\Delta H_f^\circ = -11.0$ kcal/mol for reaction (1) and its drift 4.1 ± 1.7 eu; and $\Delta H_f^\circ = 1.4$ kcal/mol for reaction (2) and its drift 21.1 ± 1.2 eu. Using the third law heats of reaction, and $\Delta H_f^\circ(\text{ZrCl}_2, \text{g}) = 49.1$ kcal/mol (6) and $\Delta H_f^\circ(\text{ZrCl}_4, \text{g}) = -207.77$ kcal/mol (2), we obtain $\Delta H_f^\circ(\text{ZrCl}_3, \text{g}) = -124.9$ kcal/mol and $\Delta H_f^\circ(\text{ZrCl}_2, \text{g}) = -43.4$ kcal/mol which are in good agreement with the values adopted.

Heat Capacity and Entropy

The molecular structure is assumed to be a pyramid similar to the group VA trichlorides. The bond distance is assumed to be the same as that of $\text{ZrCl}_4(\text{g})$. The three principal moments of inertia are $I_A = I_B = 45.9145 \times 10^{-39}$ and $I_C = 72.6247 \times 10^{-39} \text{ g cm}^2$. The electronic levels are estimated as three times higher than those of $\text{TiCl}_3(\text{g})$, based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by C. E. Moore (7). The quantum weights are assumed to be the same as those of $\text{TiCl}_3(\text{g})$.

Vibrational frequencies are calculated from the estimated force constants by the valence force method (8). The force constants are estimated from those of PCl_3 , AsCl_3 and SbCl_3 listed by Herzberg (8).

Bond Distance: $\text{Mg}-\text{Cl} = [2.18] \text{ \AA}$, $\text{Mg}-\text{Cl}(\text{ring}) = [2.3] \text{ \AA}$

Bond Angles: $\text{Cl}'-\text{Mg}-\text{Cl}(\text{in ring}) = [90^\circ]$, $\text{Cl}-\text{Mg}-\text{Cl}' = [135^\circ]$

Product of the Moments of Inertia: $I_A I_B I_C = 1.3313 \times 10^{-111} \text{ g cm}^6$

Heat of Formation

References relative to the monomer-dimer ratio in magnesium chloride vapor are given in the discussion for monomeric ideal gas. The selected best value for the heat of dimerization at 900°K is -39.2 kcal/mol. Combined with heat of formation data for the monomer and the heat capacity of the dimer, this yields $\Delta H_{298.15}^\circ = -228.10 \text{ kcal/mol}$.

Heat Capacity and Entropy

A planar structure with D_{2h} symmetry was assumed, with the outer $\text{Mg}-\text{Cl}$ distance the same as in MgCl_2 and the ring $\text{Mg}-\text{Cl}$ distance slightly larger. The ring was taken to be square, and the $\text{Cl}-\text{Mg}-\text{Cl}'$ angle 135° . This structure gives individual moments of inertia of $I_A = 31.12 \times 10^{-39} \text{ g cm}^2$, $I_B = 191.86 \times 10^{-39} \text{ g cm}^2$ and $I_C = I_A + I_B$.

A reasonable set of frequencies was estimated by comparison with MgCl_2 monomer and other dimer molecules. The single observed frequency is from A. Buchler and W. Klemperer, J. Chem. Phys. 29, 121 (1958), who erroneously ascribed it to the bending mode of the monomer. The estimated values were adjusted until the entropy of dimerization at 900°K was -29.9 gibbs/mol, as selected in the discussion for ideal monomeric gas. The calculated thermodynamic properties of monomer and dimer give total vapor pressures in good agreement with experiment and yield a boiling point for magnesium chloride of 1624°K at one atmosphere pressure.

Molybdenum Tetrachloride (MoCl₄)

(Crystal) GFW = 237.752

$$\Delta H_f^\circ = \text{Unknown}$$

$$\Delta H_{298.15}^\circ = -114 \pm 2 \text{ kcal/mol}$$

$$\Delta H_m^\circ = [4 \pm 2] \text{ kcal/mol}$$

$$S_{298.15}^\circ = [53.5 \pm 3] \text{ gibbs/mol}$$

$$T_m = 590^\circ\text{K}$$

Heat of Formation

The adopted $\Delta H_f^\circ = -114$ kcal/mol was determined by Shchukarev et al. (1) by solution calorimetry. The authors measured the heat of solution of MoCl₄ in the aqueous solvent FeCl₃ + HCl and obtained the heat of formation from a comparison with the heat of solution of MoCl₅ measured in the same solvent.

The decomposition pressures of 2MoCl₅(c) = 2MoCl₄(c) + Cl₂(g) (80 - 150°C) were measured manometrically by Saeki and Matsuzaki (2). From the reported data we evaluate the enthalpy change for the above reaction by third law analysis.

Based on ΔH_{298}° MoCl₅(c) = -126 kcal/mol and the third law $\Delta H_{298}^\circ = 24.132$ kcal/mol, we obtain ΔH_{298}° MoCl₄(c) = -113.94 kcal/mol, which is in very good agreement with the value reported by Shchukarev et al. (1).

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of WCl₄(c). The estimated $S_{298}^\circ = 53.5$ eu is based on the assumption that the entropy difference between MoCl₄(c) and MoCl₅(c) is about the same as that between WCl₄(c) and WCl₅(c). The entropy obtained from the second law analysis of the data of Saeki and Matsuzaki (2) agrees with the adopted one within the error of the vapor pressure data.

Melting Data

See liquid table.

MOLYBDENUM TETRACHLORIDE (MoCl_4)

(LIQUID)

$\text{GFW} = 237.752$

$S^\circ_{298.15} = [58.682] \text{ gibbs/mol}$

$\Delta H_f^\circ_{298.15} = [-110.621 \pm 2] \text{ kcal/mol}$

$T_m = 580^\circ\text{K}$

$\Delta H_m^\circ = [4 \pm 2] \text{ kcal/mol}$

$T_b = [580]^\circ\text{K}$

$\Delta H_v^\circ = [14.7] \text{ kcal/mol}$

Heat of Formation

The heat of formation is obtained from $\Delta H_f^\circ(c)$ by adding ΔH_m° and the difference between $H^\circ_{590} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacities are assumed to be constant at 7 gibbs/g-atom. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

T_m is taken from V. Gutmann, "Halogen Chemistry," Vol. 3, Academic Press, New York, 1987. ΔH_m° is estimated such that the derived ΔG_f° for $\text{MoCl}_4(l)$ yields a reasonable boiling point which is expected to be between 600 and 700°K from comparisons with related compounds.

Vaporization Data

T_b is the temperature at which the Gibbs energy change (ΔG_r°) of the following process $\text{MoCl}_4(l) = \text{MoCl}_4(g)$ approaches zero. The difference between ΔH_f° for $\text{MoCl}_4(l)$ and $\text{MoCl}_4(g)$ at T_b is the heat of vaporization.

Molybdenum Tetrachloride (MoCl₄)

(Ideal Gas)

GFW = 237.752

Point Group T_d $\Delta H_f^\circ = -91.8 \pm 3 \text{ kcal/mol}$ $S_{298.15}^\circ = [88.9] \text{ gibbs/mol}$ $\Delta H_f^\circ = -92.0 \pm 3 \text{ kcal/mol}$

(CRYSTAL)

S₂₉₈⁰.15 = [41.3 ± 4] gibbs/mol
Tm = 484°K
ΔHf₀⁰ = Unknown
ΔHf₂₉₈⁰.15 = -160.4 ± 2 kcal/mol
ΔHm⁰ = 10.846 ± 3 kcal/mol

Heat of Formation.

S. A. Shchukarev, I. V. Vasil'kova and G. I. Novikov¹ measured calorimetrically the heats of reaction (1) and (2) at 298°K as -131.5 ± 0.3 and -13.6 ± 0.1 kcal/mol, respectively. The reactions are given as follows:
(1) WOCl₄(c) + 6 NaOH(16.3 H₂O) → Na₂WO₄(190,000 H₂O) + 4 NaCl(50,000 H₂O) + 3 H₂O(l)
(2) H₂WO₄(c) + 2 NaOH(16.3 H₂O) → Na₂WO₄(20,000 H₂O) + 2 H₂O(l)
Based on these data and the heats of dilution for NaOH(aq)², and Na₂WO₄(aq)³, we obtain ΔHf₂₉₈⁰ = -118.0 ± 1.6 kcal/mol for WOCl₄(c) + 4OH⁻(∞H₂O) → H₂WO₄(c) + 4Cl⁻(∞H₂O) + H₂O(l). This leads to ΔHf₂₉₈⁰(WOCl₄,c) = -160.4 ± 2 kcal/mol, using ΔHf₂₉₈⁰(H₂WO₄,c) = -270.5 ± 0.4 kcal/mol⁴.

Heat Capacity and Entropy.

Cp₃₀₀ = 35.0 gibbs/mol is estimated using Kopp's rule. Since the melting point of WOCl₄(c) is approximately 500°K, which is relatively low for oxygen to reach its maximum contribution, we estimate Cp₅₀₀ = 40.0 gibbs/mol based on the values for WO₂(c), WO₃(c) and WCl₆(c).

The entropy, S₂₉₈⁰ = 41.3 eu, is calculated from ΔS₄₅₇⁰ = 44.5 eu for WOCl₄(c) → WOCl₄(g) obtained from the second law analysis of the vapor pressure equation given by S. A. Shchukarev and A. V. Suvorov⁴. See WOCl₄(g) table (Mar. 31, 1967) for details.

It is surprising that this entropy is smaller than the corresponding value for WOF₄(c). See WOF₄(c) table (Mar. 31, 1967) for details.

Melting Data.

Tm is calculated as the temperature at which the gibbs energies of formation of crystal and liquid are equal. The difference between the heats of formation of crystal and liquid at the melting point is ΔHm⁰. This ΔHm⁰ is derived from 2nd law analyses of the vapor pressure equation determined by Shchukarev and Suvorov⁴. See WOCl₄(l,g) tables (Mar. 31, 1967) for details.

TUNGSTEN OXYTETRACHLORIDE (WOCl₄)

(LIQUID)

OPW = 341.6614

S^o_{298.15} = [60.6 ± 4] gibbs/mol

ΔH^o_{298.15} = -150.711 kcal/mol

T_m = 484°K

ΔH^o_m = 10.846 ± 3 kcal/mol

T_b = 493°K

ΔH^o_v = 10.5 kcal/mol

Heat of Formation.

The heat of formation, ΔH^o_{f298}(WOCl₄, l) = -150.711 kcal/mol, is calculated from that of the gas by subtracting the heat of vaporization ΔH^o_{v298} = 13.643 kcal/mol. The latter is obtained by the third law method from the vapor pressure equation given by S. A. Shchukarev* and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). Second law analysis gives ΔH^o_{f501.9} = 10.32 kcal/mol (ΔH^o_{f298} = 13.643 kcal/mol) and the boiling point T_b = 493°K. *Earlier data reported by Shchukarev et al., Zh. Neorg. Khim. 1, 357 (1956); 2, 2630(1958); and 3, 1650 (1960), have been revised and they are not used here.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom as suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1959.

The entropy, S^o₂₉₈ = 80.8 eu, is calculated from ΔS^o_{f298} = 20.9 eu for WOCl₄(l) → WOCl₄(g) obtained from the second law analysis of the vapor pressure equation given by Shchukarev and Suvorov, loc. cit.

Melting Data.

See WOCl₄(c) table (Mar. 31, 1967) for details.

Vaporization Data.

T_b is calculated as the temperature at which the Gibbs energies of formation of liquid and gas are equal. The difference between the heats of formation of liquid and gas at the boiling point is ΔH^o_v.

Cl-W-Cl** = [180°]

*Equatorial **Axial

Product of the Moments of Inertia: I_AI_BI_C = [5.873 x 10⁻¹¹²] g³ cm⁶

Heat of Formation

The heat of formation, ΔH°₂₉₈(WOCl₄, g) = -137.0 kcal/mol, is calculated from ΔH°₂₉₈ = 23.4 kcal/mol for WOCl₄(c) → WOCl₄(g). The latter is obtained by the third law method from the vapor pressure equation given by S. A. Shchukarev* and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). Second law analysis gives ΔH°₂₉₈ = 23.4 kcal/mol.

*Earlier data reported by Shchukarev et al., Zh. Neorg. Khim. 1, 357 (1956), 3, 2630 (1956), 5, 1650 (1960), have been revised and they are not used here.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of SOP₄(g), reported by P. L. Goggin, H. L. Roberts and L. A. Woodward¹. The bond distances W-O and W-Cl are estimated to be the same as those in WO₃(g) and WOCl₂(g), respectively. The three principal moments of inertia are I_A = 8.260 x 10⁻³⁶, I_B = 1.052 x 10⁻³⁷ and I_C = 6.757 x 10⁻³⁶ g cm².

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for SOP₄(g)², WOCl₂(g)³, CrO₂Cl₂(g)^{4,5}, WO₃(g)⁶, and WOCl₆(g)⁶. The frequencies are not listed in point group order.

99 (3)

Pb-Cl distance = 2.43 Å
I_AB₂C = 7.9660 X 10⁻¹¹² g.³ cm.⁶
σ⁻ = 12

Heat of Formation. ΔH_f⁰ 298.15 was estimated from the value of ΔH_f⁰ 298.15 for PbCl₂(s), using the relation between ΔH_f⁰ 298.15 for dihalides and that for tetrahalides of titanium and zirconium as reference.

Heat Capacity and Entropy. Vibrational frequencies and molecular constants were obtained from G. Nagarajan, Bull. Soc. Chim. Belg., 71, 119 (1962).

S°_{298.15} = 49.93 ± 0.1 gibbs/mol
Tm = 249.05°K
ΔHf°₀ = -195.7 ± 1.0 kcal/mol
ΔHf°_{298.15} = -194.807 ± 1.0 kcal/mol
ΔHm° = 2.382 kcal/mol

Heat of Formation

The heat of formation, ΔHf°₂₉₈ of TiCl₄(c) is calculated from the corresponding quantity for TiCl₄(l) and the values of H°_{298.05} - H°_{298.15} for both crystal and liquid.

Heat Capacity and Entropy

The heat capacity of TiCl₄(c) has been reported by Latimer (1) and by Furukawa (2). The data from the latter investigation are adopted. These data lead to a value of 44.5 eu for S°_{249.05}. This compares with Latimer's value (1) of 43.8 eu for the same quantity. The heat capacity of the solid is extrapolated to a value of 18R at 600°K, based on the known heat capacities of TiBr₄(c) and TiI₄(c). The hypothetical entropy at 298°K is based on the integration of the extrapolated curve and the value at the melting point.

Melting Data

The triple point is reported to be 249.05°K, with a measured heat of fusion of 2.382 kcal/mol, by Furukawa (2). Latimer (1) reported values of 248.0°K and 2.233 kcal/mol for these quantities. The former data are adopted.

Heat of Formation

The heat of formation, ΔH^{f298.15}, of TiCl₄(l) is calculated from that of TiCl₄(g) and the value of ΔH_v^{298.15}. The value of ΔH_v²⁹⁸ is determined from second and third law analyses of fugacity as follows.

Source	Method	Range	No. Pts.	2nd Law	3rd Law	Drift, eu	ΔH ^f ₂₉₈

* two points rejected due to failure of a statistical test

** three points rejected due to failure of a statistical test

*** selected points from extensive data

Third law analyses of the several vapor pressure sets result in drifts which are proportional to the mean temperatures. Conversion of these data to fugacity eliminates this temperature dependence and the drifts are then scattered randomly about a constant value. This constant value is made to be essentially zero by methods described on the TiCl₄(g) table. The conversion to fugacity was made using Pitzer's method for normal fluids (5). The calculation was carried out using the value of 45.7 atm for the critical pressure, P_c, reported by Minzer (6) and estimated values of 643 ± 15°K for the critical temperature, T_c, and 0.23 ± 0.03 for the acentric constant, ω. Schafer et al. (2) reported a calorimetric determination of ΔH_v²⁹⁸. Their value of 9.9 ± 0.2 kcal/mol was used to check the reliability of their equipment, assuming that the vapor pressure data (3) gave a more accurate determination of ΔH_v²⁹⁸. The adopted value of ΔH_v²⁹⁸ is 9.82 ± 0.02 kcal/mol.

Heat Capacity and Entropy

The entropy and heat capacity of TiCl₄(l) has been measured by Furukawa (8). His reported values are adopted.

Melting Data

See TiCl₄(c) table for details.

Vaporization Data

The boiling temperature, T_b, is taken as the temperature at which K_p = 1 for the reaction TiCl₄(l) = TiCl₄(g). The vapor pressure data are discussed above.

TITANIUM TETRACHLORIDE (TiCl₄)

(IDEAL GAS)

GFW = 189.712

Point Group T_dS₂₉₈ = 84.8 ± 0.7 gibbs/mol

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies
ω, cm⁻¹ ω, cm⁻¹388 (1) 498.5 (3)
111 (2) 131 (3)Bond Distance: Ti-Cl = 2.185 Å
Bond Angle: Cl-Ti-Cl = 109° 28'Product of the Moments of Inertia: I_AI_BI_C = 4.2092 × 10⁻¹¹² g cm⁶

σ = 12

The heat of formation, ΔH_{f298}^o, of TiCl₄(g) and TiCl₄(l) has been measured by several investigators. The results of these measurements are as follows.

Investigations

Johnson et al. (1959) (1)
Farber and Darnell (1955) (2)
Shinner and Ruchwein (1955) (3)
Gross et al. (1957) (4)
Krievie et al. (1956) (5)
Thomsen (1982) (6)

-191.5±0.3 (-181.7)
-190.0±0.4 (-180.2)
-194.5 (-184.7)The chosen value of ΔH_{f298}^o is that reported by Johnson et al. (1). This investigation has the advantage of being independent of the heat of vaporization of chlorine and any heats of solution in deriving the value of the heat of formation.

Heat Capacity and Entropy

The adopted value for the interatomic distance is that reported by Kimura et al. (2). The tetrahedral structure was established by the Raman work of Bhagavantam (3). The vibrational frequencies determined from the infrared and Raman spectra of TiCl₄ by Hawkins and Carpenter (3) are adjusted downward 8 cm⁻¹ for ν₂ and ν₄ so that the heats of vaporization determined by both second and third law methods are in agreement. See TiCl₄(l) table for details. The principal moments of inertia are: I_A = I_B = I_C = 74.943 × 10⁻³⁹ g cm².

ΔHf° = Unknown

ΔHf°_{298.15} = -105.9 ± 15 kcal/molS°_{298.15} = [47.4] gibbs/mol

Td = [771]°K

Heat of Formation.

The heat of formation, ΔHf°₂₉₈(WCl₄, c) = -105.9 kcal/mol, is calculated from ΔHf°₂₉₈ = 58.9 kcal/mol for 3WCl₄(c) = WCl₂(c) + 2WCl₅(g). The value of ΔHf°₂₉₈ is calculated by the third law method from decomposition pressure data in the temperature range from 354°C to 436°C reported by S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The second law ΔHf°₂₉₈ = 73.6 ± 7.9 kcal/mol and the third law drift is -24 ± 12 eu, which would correspond to a total entropy discrepancy of -8 ± 4 eu per mole of WCl₄. This entropy discrepancy is probably within the combined uncertainty of the data and the estimated entropies for the three species. S. A. Shchukarev et al., Vestnik Leningrad. Univ. 14, No. 10, Ser. Fiz. i Khim., No. 2, 78 (1959), have shown that decomposition pressures are essentially independent of the composition in the solid phase until WCl₄(c) is almost completely decomposed to WCl₂(c). This is consistent with the assumption of solid phase activities of unity which we have used in the equilibrium analysis.

Heat Capacity and Entropy.

Cp₂₉₈ = 8.2 gibbs/g-atom and Cp₇₀₀ = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 700°, which is near the decomposition temperature, the heat capacity is obtained by linear interpolation.

The entropy of WCl₄(c), S°₂₉₈ = 47.4 eu, is estimated by the method of W. M. Latimer, "Oxidation Potentials," 2nd Ed., Prentice-Hall, Inc., New York, 1952.

Temperature of Decomposition.

Td is calculated as the temperature at which the Gibbs energy change of the reaction 3 WCl₄(c) = WCl₂(c) + 2 WCl₅(g) approaches zero. We have also derived an approximate value of decomposition temperature, Td = 744°K, by extrapolation to one atmosphere total pressure of a log P versus 1/T fit of the decomposition pressure data reported by S. A. Shchukarev et al., Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The difference between the two decomposition temperatures is related to the second law entropy and the adopted entropy.

Cl₄W

(CRYSTAL)

ZIRCONIUM TETRACHLORIDE (ZrCl₄)

GFV = 233.032

Zirconium Tetrachloride (ZrCl₄)

GFV = 233.032

S_{298.15} = 43.36 ± 0.7 gibbs/mol $\Delta H_f^\circ = -234.42 \pm 0.28$ kcal/mol $\Delta H_f^\circ = -234.17 \pm 0.28$ kcal/mol $\Delta H_m = 12 \pm 3$ kcal/mol $\Delta H_{s,298.15}^\circ = 26.4 \pm 0.3$ kcal/molT₀ = 606.8°KT_m = 710°K

Heat of Formation

Gal'chenko et al. (1) determined the heat of formation of ZrCl₄(c) by the direct chlorination of the highly pure Zr metal in a bomb calorimeter. Complete chlorination of the metal was accomplished as indicated by the absence of unreacted metal and of lower chlorides. Their value, $\Delta H_f^\circ(\text{ZrCl}_4, c) = -234.17 \pm 0.28$ kcal/mol, is adopted in the tabulation.

Gross et al. (2) measured calorimetrically $\Delta H_{298}^\circ = -225.89$ kcal/mol for Zr(c) + 2Cl₂(g) + ZrCl₄(c). Corrections for the difference in heat content between liquid and gaseous chlorine at 25°C and 1 atm led to the value of standard heat of formation, $\Delta H_f^\circ(\text{ZrCl}_4, c) = -234.7 \pm 0.4$ kcal/mol, which is in good agreement with the value adopted. Siemonsen and Siemonsen (3) also measured the heat of formation by direct chlorination of the metal in an enameled bomb calorimeter. However, they did not report their detailed experimental procedure, neither the purity of their sample, nor the corrections. The value was given as $\Delta H_{298}^\circ = -231.9 \pm 0.5$ kcal/mol.

Heat Capacity and Entropy

Todd (4) measured the low temperature heat capacities from 52.6 to 296.7°K, and made an extrapolation to 0°K which yielded an entropy of 8.12 eu at 51°K. We have adopted the measured heat capacities, but have made our own extrapolation to 0°K, based on the ratio of the measured heat capacities of ZrF₄ (5), TiF₄ (6), and TiCl₄ (7) from 6° to 50°K. This extrapolation gives S₅₀ = 6.758 ± 0.7 eu which is used in the table. Coughlin and King (8) measured high temperature enthalpy data from 335.9° to 566.8°K by drop calorimetry. Their data are smoothly joined with Todd's low temperature heat capacities and adopted in the table.

Melting Data

The melting point, 710°K, has been observed by Rahlfs and Fischer (9), Palko et al. (10), Denisova et al. (11, 12).

Palko et al. derived the heat of melting as 9 ± 2.5 kcal/mol from their vapor pressure data. Denisova et al. (11, 12) determined thermographically the heat of melting as 14 ± 3 kcal/mol and also determined the heat of vaporization at 710°K as 10.4 kcal/mol combined with the heat of sublimation at 710°K (23.8 kcal/mol) gives the heat of melting as 13.4 kcal/mol. A weighted average 12 ± 3 kcal/mol is adopted for the heat of melting.

Heat of Sublimation

Several investigators have measured the vapor pressure of ZrCl₄(c) by the static method. Second and third law analyses for the vapor pressure data are summarized below:

Source	No. of Points	Temperature Range (°K)	$\Delta H_{s,298}^\circ$ (kcal/mol)	Drift (eu)
Rahlfs and Fischer (9)	11	535-607	27.516	26.379
Palko et al. (10)	86*	500-689	26.255	26.435
Denisova et al. (11)	17**	628-708	26.515	26.376
				44.81
				-0.29±0.51

* 4 points rejected due to failure of a statistical test.

** 1 point rejected due to failure of a statistical test.

The third law value, $\Delta H_{s,298}^\circ = 26.4$ kcal/mol, is adopted in the tabulation.

The sublimation temperature is obtained from the Gibbs free energy crossover between solid and gas. Rahlfs and Fischer (9) reported the sublimation temperature as 604°K.

Since the sublimation temperature is lower than the melting point, the liquid phase is thermodynamically unstable at normal conditions.

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
376 (1)	418 (3)
99 (2)	110 (3)

Bond Distance: Zr-Cl = $2.32 \pm 0.02 \text{ \AA}$
Bond Angle: Cl-Zr-Cl = 109.2°
Product of the Moments of Inertia: $I_A I_B I_C = 6.03177 \times 10^{-112} \text{ g cm}^6$ $\sigma = 12$

Heat of Formation

The heat of formation of gaseous ZrCl_4 , $\Delta H_f^\circ = -207.77 \pm 0.2 \text{ kcal/mol}$, is calculated from the heat of formation of the crystal and the formation derived from vapor pressure data. (See JANAF ZrCl_4 (c) table dated Dec. 31, 1969). Hildenbrand et al. (1) determined the equilibrium constants by the transpiration method for the reaction:

Second and third law analyses for their data are given below:

Series	No. of Points	Temp. Range (°K)	ΔH_{298}° (kcal/mol)	Drift (eu)	ΔH_{298}° (g) (kcal/mol)
I	10	1171-1375	28.853	29.321	-205.6
II	9	1189-1374	31.397	30.007	-205.0

*Derived from third law ΔH_{298}° and ΔH_{298}° (ZrO_2 , c) = -262.3 kcal/mol , ΔH_{298}° (HCl , g) = -22.063 kcal/mol and ΔH_{298}° (H_2O , g) = -57.798 kcal/mol .

The derived heat of formation is in fair agreement with the value adopted.

Heat Capacity and Entropy

Spiridonov et al. (2) measured the bond distance $\text{Zr-Cl} = 2.32 \pm 0.02 \text{ \AA}$ in the vapor phase by electron diffraction. The molecule was also found to be a regular tetrahedron. The same bond distance was also reported by Lister and Sutton (3) and Kimura et al. (4). The three principal moments of inertia are $I_A = I_B = I_C = 84.4942 \times 10^{-39} \text{ g cm}^2$.

Wilmschurst (5) observed one fundamental vibrational frequency ($\nu_3 = 421 \text{ cm}^{-1}$) in the infrared spectrum of ZrCl_4 vapor, and made reasonable estimates ($\nu_1 = 388$, $\nu_2 = 102$ and $\nu_4 = 112 \text{ cm}^{-1}$) for the three remaining unobserved fundamentals, based on observed overtone and combination bands. Godnev et al. (6) calculated the four fundamental vibrational frequencies (382, 108, 423 and 114 cm^{-1}) from data for related group IV halides through the use of a 5-parameter potential function. Büchler et al. (7) also found in the infrared spectrum the vibrational frequency, $\nu_3 = 423 \text{ cm}^{-1}$. Delvaule and Francois (8) observed the symmetric stretching vibration ν_1 at 383 cm^{-1} from the Raman spectrum of ZrCl_4 in PCl_3 and POCl_3 , both of which form complexes with ZrCl_4 . Bobovich (9) reported the symmetric stretching vibration ν_1 at 315 cm^{-1} from a partially polarized band in his Raman spectrometric studies.

Pontrelli (10) observed in the Raman spectrum all four fundamental vibrational frequencies (376, 99, 418 and 110 cm^{-1}) which are adopted in the tabulation.

Cl₅Mo

MOLYBDENUM PENTACHLORIDE (MoCl₅) (CRYSTAL)

GTW = 273.205

$\Delta H_f^\circ =$ unknown

$\Delta H_{298.15}^\circ = -126 \pm 2$ kcal/mol

$\Delta H_m^\circ = [4.5 \pm 1.5]$ kcal/mol

$S_{298.15}^\circ = [57 \pm 3]$ gibbs/mol

$T_m = 467^\circ K$

Heat of Formation

The heat of formation is obtained from S. A. Shchukarev, G. I. Novikov, I. V. Vasil'kova, A. V. Suvorov, N. V. Andreeva, B. N. Sharupin, and A. K. Baev, Zh. Neorg. Khim. 5, 1650 (1960). The authors derived the ΔH_f° (MoCl₅, c) = -126 kcal/mol by measuring the heat of solution of MoCl₅ in NaOH(aq), which was compared with the heats of solution of MoO₃ and NaCl measured in the same solvent.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with that of HCl₅(c). S_{298}° is estimated as 57 eu from the vapor pressure data for MoCl₅(c) + MoCl₅(g) measured by S. A. Shchukarev, I. V. Vasil'kova and B. N. Sharupin, J. Gen. Chem. USSR (English Transl.) 26, 2335 (1956).

MOLYBDENUM PENTACHLORIDE (MoCl₅)S_{298.15}^o = [65.441] gibbs/mol ΔH_f° _{298.15} = [-121.9205] kcal/mol ΔH_m° = [4.5 ± 1.5] kcal/molT_m = 467°K ΔH_v° = [12.0] kcal/molT_b = 537°K

Heat of Formation

The heat of formation is obtained from ΔH_f° (c) by adding ΔH_m° and the difference between H_{lm}° - H_{298}° for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is assumed constant and estimated as 42 gibbs/mol or 7 gibbs/g-atm. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

T_m is taken from S. A. Shchukarev, G. I. Novikov, A. V. Suvorov and V. K. Moksimov, Russ. J. Inorg. Chem. (English Transl.) 4, 935 (1959). ΔH_m° is estimated by comparison with that of WCl₅(c).

Vaporization Data

T_b is the temperature at which the difference between the Gibbs energy of formation for MoCl₅(l) and MoCl₅(g) approaches zero. The difference between ΔH_f° (MoCl₅, l) and ΔH_f° (MoCl₅, g) is ΔH_v° .

Heat of Formation

The adopted $\Delta H_{298}^\circ = -107.0$ kcal/mol is obtained from the vapor pressure data for $\text{HocCl}_5(\text{c}) = \text{HocCl}_5(\text{g})$ measured by Shchukarev et al. (1) and Saeki and Matsuzaki (2).

Source	Method	Reaction	Temperature Range, °K	ΔH_{298}° , kcal/mol	Drift e.u.	ΔH_{298}° kcal/mol
Shchukarev	Transpiration	$\text{MoCl}_5(\text{c}) = \text{MoCl}_5(\text{g})$	343 - 435	19.04 ± 0.45	0.3	-106.82
Saeki	Manometric	$\text{MoCl}_5(\text{c}) = \text{MoCl}_5(\text{g})$	298 - 474	16.79 ± 0.06	5.6	-107.06

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of NBCl_2 obtained from infrared and Raman spectra by Carlson (3). Structure, bond distance and bond angle are taken from Evans et al. (4). The three principal moments of inertia are $I_A = I_B = 106.1682 \times 10^{-39}$ and $I_C = 91.0074 \times 10^{-39}$ g cm². The electronic levels are estimated to be 0, 7000 and 4000 cm⁻¹, all doublets, by comparison with those of WCl_2 (g).

TUNGSTEN PENTACHLORIDE (WCl₅) (CRYSTAL)

GFW = 361.115

ΔH_f⁰ = UnknownΔH_f⁰_{298.15} = -122.6 ± 10 kcal/molΔH_m⁰ = 4.917 ± 1 kcal/molΔH_s⁰_{298.15} = 24.0 kcal/molS°_{298.15} = [52.0] gibbs/molT_m = 526°K

Heat of Formation.

The heat of formation, ΔH_f⁰ (WCl₅, c) = -122.6 kcal/mol, is calculated from that of the gas less the heat of sublimation, ΔH_s⁰₂₉₈ = 24.0 kcal/mol. The latter is calculated by the third law method from partial pressures of WCl₅(g) derived from the total pressure data* of S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4 Ser. Fiz. i Khim., No. 1, 120 (1959). Dimer pressures, calculated from the same authors' dimer-monomer dissociation data, are subtracted from the total pressures in order to obtain the monomer pressures. Analyses of the monomer pressures over both crystal and liquid give similar results and the average values for ΔH_s⁰₂₉₈ are 20.6 (second law) and 24.0 kcal/mol (third law) with a drift of about 7 eu.

*Earlier data reported by Shchukarev et al., Zhur. Neorg. Khim. 1, 357 (1956); 2, 2630 (1958), have been revised and are not used here.

Heat Capacity and Entropy.

Cp₂₉₈ = 6.2 gibbs/g-atom and Cp₅₂₆ = 7.25 gibbs/g-atom are estimated using the method described by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1958. Between 298° and 526°, which is the melting point, the heat capacity is obtained by linear interpolation.

The entropy, S°₂₉₈ = 52 eu, is estimated by comparison with those of WCl₂ (c), WCl₄ (c) and WCl₆ (c).

Melting Data.

The melting point was determined from vapor pressure data by Shchukarev et al., loc. cit. The heat of melting is the difference at the melting point between the second law heats of vaporization and sublimation derived from total vapor pressure data of Shchukarev et al., loc. cit.

Heat of Sublimation.

See the heat of formation of WCl₅(g) for details.

Dec. 31, 1962; Dec. 31, 1966

ΔH_f^o_{298.15} = -118.4 kcal/mol

ΔH_m^o = 4.917 ± 1 kcal/mol

ΔH_v^o = 16.266 kcal/mol

Heat of Formation.

The heat of formation, ΔH_f^o₂₉₈ (WCl₅(l)) = -118.4 kcal/mol, is calculated from that of WCl₅(c) by adding the heat of melting and the difference between H₅₂₆^o - H₂₉₈^o for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom.

The entropy of WCl₅(l), S_{298.15}^o = 59.393 eu, is calculated in a manner analogous to that of the heat of formation.

Melting Data.

See WCl₅(c) table for details.

Vaporization Data.

The boiling point, 561.4°K is calculated as the temperature at which the gibbs energy of formation for both WCl₅(l) and WCl₅(g) are equal. The difference in the heats of formation of WCl₅(l) and WCl₅(g) at the boiling point is the heat of vaporization. S. A. Shchukarev, G. I. Novikov and N. V. Andreeva¹ revised their previous data² and derived the boiling point as 561.2°K from their vapor pressure measurements.

Bond Distance: W-Cl = [2.26] Å

Bond Angle: Cl-W-Cl* = [120]° Cl*-W-Cl** = [180]°

* Equatorial ** Axial

Product of the Moments of Inertia: I_AI_BI_C = [9.98 x 10⁻¹¹²] g³ cm⁶

σ° = [6]

Heat of Formation

The heat of formation, ΔH°_{f,298} (WCl₅, g) = -98.6 kcal/mol, is calculated from ΔH°_{f,298} = 19.4 kcal/mol for WCl₆(g) → WCl₅(g) + 1/2 Cl₂(g). The value of ΔH°_{f,298} is calculated by the third law method from the equation for log Kp given by S. A. Shchukarev and A. V. Suvorov, Vestnik Leningrad. Univ. 16, No. 4, Ser. Fiz. i Khim., No. 1, 87 (1961). The second law ΔH°_{f,298} is 24.6 kcal/mol and the third law drift is -8.5 eu.

Heat Capacity and Entropy

The molecular configuration is assumed to be a trigonal bipyramid similar to that of MoCl₅ determined by electron diffraction by R. V. G. Evans and M. W. Lister, Trans. Faraday Soc. 34, 1358 (1938). The bond distance is estimated to be the same as that in WCl₆(g). The three principal moments of inertia are: I_A = I_B = 105.23 x 10⁻³⁹ and I_C = 90.20 x 10⁻³⁹ g cm².

All vibrational frequencies are estimated from those of SbCl₅, PCl₅, NbCl₅ and TaCl₅ obtained from infrared and Raman spectra by G. L. Carlson, Spectrochim. Acta 19, 1291 (1963).

If it is considered that the metal atoms are effectively ionized, then the W⁵⁺ will have a single d electron in a field of chloride ions. The electronic splitting would be roughly the inverse of that in CuCl₂(g) as given by C. W. DeKock and D. M. Gruen, J. Chem. Phys. 45, 4387 (1966), where Cu has a d⁹ configuration. By analogy with the splitting in CuCl₂, the low lying electronic levels are estimated to be 7000 cm⁻¹ and 14000 cm⁻¹, both doublets.

Heat of Formation.

The vaporization of FeCl₃(c) is complex. It involves three possible chemical reactions, i.e. (1) 2FeCl₃(c) = Fe₂Cl₆(g); (2) FeCl₃(c) = FeCl₂(g) + Cl₂(g); and (3) 2FeCl₃(c) = 2FeCl₂(g) + Cl₂(g). Although these equilibria have been studied previously by many investigators, a review of their reported data reveals inconsistencies and errors. At room temperature the main vapor species present above FeCl₃(c) is Fe₂Cl₆(g), a dimer of FeCl₃(g). As temperature increases, the dimer gradually decomposes into monomers (FeCl₃·g). Simultaneously, part of FeCl₃(c) also decomposes into FeCl₂(g) and Cl₂(g). Therefore in order to obtain the partial pressure of Fe₂Cl₆(g), the partial pressures of other vapor species, e.g. Cl₂(g) and FeCl₃(g), must be known and deducted from the observed total pressures. However, only few investigators made such corrections. The total pressures above FeCl₃(c), at 500-600°K., have been determined by Maier¹ and Johnston², respectively. The partial pressures of Fe₂Cl₆(g) were evaluated by the subtraction of the calculated equilibrium pressures of Cl₂(g) obtained from reaction (3), from the reported total pressures. The partial pressures of FeCl₃(g) were found to be insignificant at these temperatures. Using the partial pressures obtained for Fe₂Cl₆(g), the enthalpy change (ΔH°_f 298.15°) of reaction (1) was derived by both the second and third law methods. Then the value of ΔH°_f 298.15° (Fe₂Cl₆·g) was calculated. The results are given in the table.

Wilson and Gregory³ have investigated the vaporization and thermal decomposition equilibria of FeCl₃(c) by gas saturation flow and diaphragm gage techniques. Using the partial pressures for Fe₂Cl₆(g), calculated from an equation, the values of ΔH°_f 298.15° and ΔH°_f 298.15° were also evaluated and listed in the table. Based on the total pressures measured by Stirrman⁴ and Sano⁵, the equations for the pressures of Fe₂Cl₆(g) and Cl₂(g) in equilibrium with FeCl₃(c) and FeCl₂(c) as a function of temperature were reported by Wilson and Gregory³. The corresponding values of ΔH°_f 298.15° and ΔH°_f 298.15° were hence calculated. A brief summary and discussion of results of some other previous investigators were also given in the same report.

Investigator	Temperature, °K.	Second Law Value	Third Law Value	ΔH° _f 298.15° kcal. mole ⁻¹
Maier ¹	489.6-591.5	32.18 ± 0.40	34.67	-156.25 ± 0.50
Johnston, et al. ²	505.2-562.2	34.61 ± 0.49	34.50	-156.42 ± 0.50

1 C. O. Maier, U. S. Bur. Mines Tech. Paper 380 (1925).

2 H. P. Johnston, H. C. Weingartner and W. E. Mirache, J. Am. Chem. Soc. **64**, 241 (1942).3 L. E. Wilson and N. W. Gregory, J. Phys. Chem. **52**, 435 (1958).4 E. Stirrman, Neues Jahrb. Mineral., Geol., Palsont., **52A**, 334 (1925).5 K. Sano, J. Chem. Soc. Japan, **59**, 1073 (1958).The value of ΔH°_f 298.15° for Fe₂Cl₆(g) is selected as -156.4 ± 2.0 kcal. mole⁻¹.

Heat Capacity and Entropy.

The molecular structure, bond distances and angles were obtained from E. Z. Zasorin, N. O. Rembid and P. A. Alkhin, Zh. Strukt. Khim., **4**, 910 (1963). The vibrational frequencies were estimated by comparison with those for Al₂Cl₆(g) such that the values of ΔH°_f derived from the equilibrium data by the second and third law methods are in reasonable agreement. The three principal moments of inertia are: I_A = 2.79395 × 10⁻³⁷, I_B = 1.16349 × 10⁻³⁷ and I_C = 2.26383 × 10⁻³⁷ g. cm.²

Molybdenum Hexachloride (MoCl₆)

GFW = 308.658

MOLYBDENUM HEXACHLORIDE (MoCl₆)

(CRYSTAL)

GFW = 308.658

 $\Delta H_f^\circ = \text{unknown}$ $\Delta H_{298.15}^\circ = [-125 \pm 10] \text{ kcal/mol}$ $S_{298.15}^\circ = [61.0 \pm 4.0] \text{ gibbs/mol}$ $T_s = [527]^\circ\text{K}$

Heat of Formation

G. I. Novikov and N. V. Galitskii, Zh. Neorg. Khim. 10, 576-8 (1965), assumed that the equilibrium $\text{MoCl}_5(\text{c}) = \text{MoCl}_3(\text{g}) + 1/2 \text{Cl}_2(\text{g})$ exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics. $\Delta H_f^\circ = 4 \text{ kcal/mol}$ and $\Delta S_{298}^\circ = 8 \text{ eu}$, of the equilibrium $\text{MoCl}_5(\text{c}) = \text{MoCl}_3(\text{c}) + 1/2 \text{Cl}_2(\text{g})$, from which they obtained the $\Delta H_{298}^\circ(\text{MoCl}_5, \text{c}) = -125 \text{ kcal/mol}$.

Heat Capacity and Entropy

The adopted heat capacity is the same as that of $\text{WCl}_5(\text{g}, \text{c})$, since the heat capacities of W and Mo are almost the same. The entropy is estimated from that of $\text{MoCl}_5(\text{c})$ by the addition of 4 eu due to one extra chlorine atom in the molecule.

Vaporization Data

The sublimation point is calculated from the free energy crossover between crystal and gas. However, it should be noted that $\text{MoCl}_5(\text{c})$ is unstable with respect to $\text{MoCl}_3(\text{c})$ at all temperatures and thus sublimation could occur only under an atmosphere of Cl_2 .

Heat of Formation

G. I. Novikov and N. V. Galitskii, Zh. Neorg. Khim. **10**, 576-82 (1965), assumed that the equilibrium $\text{MoCl}_5(\text{c}) = \text{MoCl}_5(\text{g}) + 1/2 \text{Cl}_2(\text{g})$ exists. They then calculated values for the constant of the above equilibrium and estimated the thermodynamic characteristics, $\Delta H_f^\circ = 2.5 \text{ kcal/mol}$ and $\Delta S_f^\circ = 10 \text{ eu}$ of the equilibrium $\text{MoCl}_5(\text{g}) = \text{MoCl}_5(\text{g}) + 1/2 \text{Cl}_2(\text{g})$, from which they obtained the $\Delta H_{298}^\circ(\text{MoCl}_5 \text{ g}) = -105 \text{ kcal/mol}$.

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those of MoF_6 and WF_6 , given by K. Nakamoto, "Infrared Spectra of Inorganic and Coordination Compounds," John Wiley and Sons, Inc., New York - London, 1963, and WCl_6 given by J. C. Evans and G. Y. S. Lo, J. Mol. Spectrosc. **28**, 147 (1968).

Structure, bond distance and bond angle are estimated to be the same as those of WCl_6 . The three principal moments of inertia are $I_A = I_B = I_C = 120.2684 \times 10^{-39} \text{ g cm}^2$.

TUNGSTEN HEXACHLORIDE, ALPHA (α -WCl₆) (CRYSTAL)

OPW = 396.568

Cl₆W

ΔH°_0 = Unknown
 $\Delta H^\circ_{298.15} = -141.9 \pm 6 \text{ kcal/mol}$
 $\Delta H^\circ (a_1 \rightarrow a_2) = [1.0] \text{ kcal/mol}$
 $\Delta H^\circ (a_2 \rightarrow \beta) = 3.77 \text{ kcal/mol}$
 $\Delta H^\circ_{298.15} = 23.9 \text{ kcal/mol}$

$S^\circ_{298.15} = [57.0] \text{ gibbs/mol}$
 $Tt (a_1 \rightarrow a_2) = 450 \pm 10^\circ\text{K}$
 $Tt (a_2 \rightarrow \beta) = 503 \pm 3^\circ\text{K}$

Heat of Formation.

S. A. Shchukarev, I. V. Vasilkova and G. I. Novikov, Zh. Neorg. Khim., 3, 2642 (1958), have measured calorimetrically the heat of solution of WCl₆(c) and also of H₂WO₄(c) in a 12% solution of NaOH as -188.0 ± 0.3 and -13.6 ± 0.11 kcal/mol, respectively. Based on these data and a heat of dilution value for Na₂WO₄ which is essentially zero, we obtain $\Delta H^\circ_{298} = -174.4 \pm 0.3 \text{ kcal/mol}$ for WCl₆(c) + 6NaOH(18.3H₂O) → H₂WO₄(c) + 6NaCl(22.00H₂O) + 2H₂O(l). This reaction gives from JANAP Tables and from V. B. Parker, "Thermal Properties of Aqueous Unit-univalent Electrolytes," NSRDS-NBS2, Natl. Bur. Std., Washington, D.C., April, 1965. The authors have suggested a possible uncertainty of the order of 5 kcal/mol due to the slowness of the dissolution of WCl₆(c).

Heat Capacity and Entropy.

J. R. Welty¹ has measured the enthalpy changes for WCl₆(a,c) in the temperature range from 405° to 502.4°K by drop calorimetry. Few points were measured in the region of the $a_1 \rightarrow a_2$ transition and no attempt was made to investigate the phase present at the conclusion of the drop. Thus, these data appear to be inadequate to define the heat capacities of the a_1 and a_2 phases. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy $S^\circ_{298} = 57.0 \text{ eu}$, is calculated from that of the gas using $\Delta S^\circ_{298} = 43.155 \text{ eu}$ from the vaporization and sublimation data given in the WCl₆(g) table (December 31, 1966).

Transition Data.

Transition temperatures and heats of transition have been reported by the following investigators, and their results are summarized as follows:

Investigator	Method	$a_1 \rightarrow a_2$ transition		$a_2 \rightarrow \beta$ transition	
		Temperature (°K)	ΔH° (kcal/mol)	Temperature (°K)	ΔH° (kcal/mol)
Ketelaar ² et al.	Vapor pressure	441	-	500	3.4
Stevenson ³	Cooling curve	458	-	503	-
Welty ¹	Vapor pressure	-	-	503	1.9
Shchukarev ⁴ et al.	Drop calorimetric	-	-	504	3.4
Dobrotin ⁵	Vapor pressure	-	-	504	3.4
	Approximate calorimetric	-	-	493 ± 10	5.5

The adopted $\Delta H^\circ_{450} (a_1 \rightarrow a_2)$ and $\Delta H^\circ_{503} (a_2 \rightarrow \beta)$ are calculated as 1.0 and 3.77 kcal/mol, respectively, based on the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to a_1 phase as the final state, although no experimental evidence for this is given.

Melting Data.

See WCl₆ (p.c) table (December 31, 1966).

Heat of Sublimation.

See WCl₆(g) table (December 31, 1966) for detailed information about sublimation data.

The entropy of $WCl_6(\beta, c)$, $S^\circ_{298.15} = 67.066$ eu, is calculated in a manner analogous to that of the heat of formation.

Transition Data.

See $WCl_6(g, c)$ table (Dec. 31, 1966).

Melting Data.

Melting point and heat of melting have been reported by the following investigators, and their results are summarized as follows:

Investigator	Method	Melting Point (°K)	ΔH_m° (kcal/mol)
Ketelaar ² et al.	Vapor pressure	557	2.3
Stevenson ³	Cooling curve	555	-
Welty ¹	Vapor pressure	555	1.5
Shchukarev ⁴ et al.	Drop calorimetric	556	1.6
Dobrotin ⁵ et al.	Vapor pressure	564	2.0
	Approximate calorimetric	545 ± 12	4.2

The adopted heat of melting, $\Delta H_{555}^\circ = 1.6$ kcal/mol, is calculated from the adopted heat capacities and the enthalpy data. The enthalpies are assumed to refer to α_1 phase as the final state, although no experimental evidence for this is available.

Heat of Sublimation.

$\Delta H_{298.15}^\circ$ is calculated as the difference between $\Delta H_{298.15}^\circ$ for $WCl_6(\beta, c)$ and $WCl_6(g)$.

Heat of Formation.

The heat of formation, $\Delta H^\circ_{298.15}(\text{WCl}_6(l)) = -136.091 \text{ kcal/mol}$, is calculated from that of $\text{WCl}_6(\beta, c)$ by adding the heat of melting and the difference between $H^\circ_{555} - H^\circ_{298.15}$ for $\text{WCl}_6(\beta, c)$ and $\text{WCl}_6(l)$.

Heat Capacity and Entropy.

J. R. Welty, Ph.D. Thesis, Oregon State University (1962), has measured the enthalpy changes for $\text{WCl}_6(l)$ in the temperature range from 560° to 603°K by drop calorimetry. Since the temperature range was very short and no attempt was made to investigate the phase present at the conclusion of the drop, we feel that the enthalpy data are insufficient to define the heat capacity accurately. The adopted heat capacities are estimated so that they are reasonably consistent with the enthalpy data.

The entropy of $\text{WCl}_6(l)$, $S^\circ_{298.15} = 68.085 \text{ eu}$, is calculated in a manner analogous to that of the heat of formation.

Melting Data.

See $\text{WCl}_6(\beta, c)$ table dated Dec. 31, 1966.

Vaporization Data.

The boiling point, 613.6°K, is calculated as the temperature at which the Gibbs energies of formation for both $\text{WCl}_6(l)$ and $\text{WCl}_6(g)$ are equal. The difference in the heats of formation of $\text{WCl}_6(l)$ and $\text{WCl}_6(g)$ at the boiling point is the heat of vaporization.

J. A. A. Ketelaar, G. W. Oosterhout and P. B. Braun, Rec. Trav. Chim. 82, 597 (1943), have determined the boiling point and the heat of vaporization as 609.7°K and 15.24 kcal/mol, respectively, from vapor pressure measurements. S. A. Shchukarev and A. V. Suvorov revised their previous data^{2,3} and gave the boiling point and the heat of vaporization as 616.2°K and 14.7 kcal/mol, respectively, from their vapor pressure measurements.

See $\text{WCl}_6(g)$ table, dated Dec. 31, 1966, for detailed information about vaporization data.

Heat of Formation

The heat of formation of WCl₆(g), ΔH_f⁰₂₉₈ = -118.0 kcal/mol, is calculated from that of the crystal plus the adopted heat of sublimation, ΔH_{sub}⁰₂₉₈ = 23.9 kcal/mol for WCl₆(s) → WCl₆(g). The latter was obtained from third law analysis of the vapor pressure data 1,2,3,4, using all JANAP functions (Dec. 31, 1966).

A. A. Vernon⁴ has also determined the equilibrium constants in the temperature range from 1360° to 1600°K for the decomposition of WCl₆(g) to W(c) and Cl₂(g) by reaction of the sample with a hot tungsten filament in a vacuum bulb. Using the reported equilibrium constants, the heat of formation of WCl₆(g) at 298°K is calculated by the second and third law method as -131.8 ± 2.9 kcal/mol and -135.2 kcal/mol, respectively. The third law drift is 2.4 ± 1.9 eu. Unfortunately, the reported equilibrium constants may be seriously in error, since atomic chlorine is the main species at the pressure and temperature studied.

* Enthalpy changes are converted to ΔH_f⁰₂₉₈ for WCl₆(α, c) → WCl₆(g).

** Vapor pressure equations for the crystal (α,β) and the liquid to gas are given.

*** The third law ΔH_f⁰₂₉₈ is used in calculation.

Heat Capacity and Entropy.

R. G. Owens and M. W. Lister, Trans. Faraday Soc. 35, 1358 (1939), have determined the octahedral structure for WCl₆(g) by electron diffraction and found the bond length to be 2.26 Å.

The vibrational frequency of ν₃, 375 cm⁻¹, was observed in the infrared spectra by J. C. Evans, The Dow Chemical Company, private communication, Dec. 1, 1966. The values of ν₁, ν₂ and ν₅ (360, 340 and 180 cm⁻¹, respectively) are estimated, based on those of the aqueous ion PtCl₆²⁻ reported by L. A. Woodward and J. A. Creighton, Spectrochim. Acta 17, 594 (1961). The values of ν₄ and ν₆ (140 and 120 cm⁻¹, respectively) are estimated by comparison with those of Wp₆(g).

The three principal moments of inertia are I_A = I_B = I_C = 120.2684 x 10⁻³⁹ g cm².

*Equatorial **Axial

Product of the Moments of Inertia: $I_A I_B I_C = [8.638] \times 10^{-110}$ g³ cm⁶

Heat of Formation

The heat of formation, $\Delta H^\circ_{298} (W_2Cl_{10}(g)) = -207.6$ kcal/mol, is calculated from $\Delta H^\circ_{298} = 10.4$ kcal/mol for $WCl_5(g)$, using all JANAF functions (Dec. 31, 1966). The value of ΔH°_{298} is obtained from third law analysis of the partial pressures of $WCl_5(g)$ and $W_2Cl_{10}(g)$ derived from PVT data determined by S. A. Shchukarev, G. I. Novikov and N. V. Andreeva, Vestnik Leningrad. Univ. 14, No. 4, Ser. Fiz. i Khim., No. 1, 120 (1959). The second law ΔH°_{298} is 10.4 ± 0.3 kcal/mol.

Heat Capacity and Entropy

The molecular configuration is estimated by analogy with that of Mo_2Cl_{10} reported by D. Z. Sands and A. Zaikin, Acta Cryst. 12, 723 (1959). Chlorine atoms are placed octahedrally around two tungsten atoms and these two octahedra share one common edge with six chlorine and two tungsten atoms in a plane. The bond length is estimated to be the same as that in $WCl_5(g)$. The three principal moments of inertia are $I_A = 210.5 \times 10^{-39}$, $I_B = 576.8 \times 10^{-39}$ and $I_C = 546.8 \times 10^{-39}$ g cm².

All vibrational frequencies are estimated, based on those of WCl_5 , $(AlCl_3)_2$ and Ca_2Cl_6 , such that $S^\circ_{50}(W_2Cl_{10}(g)) = 216.65$ eu. This entropy is derived from $\Delta S^\circ_{50} = 19.92 \pm 0.5$ eu for $W_2Cl_{10}(g) = 2WCl_5(g)$, obtained by second law analysis of the data of Shchukarev et al., loc. cit. The frequencies are not in point group order.

$Cl_{10}W_2$

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The heat capacity of Co(c) is adopted from Hultgren et al. (1). Their selected values are based on the data from nineteen investigations. The entropy values are based on S₁^o = 0.0011 eu. The heat capacity has a maximum value of 13.14 gibbs/mol at the Curie point (1394°K).

Transition Data

The exact nature of the α(hcp)-β(fcc) transition is yet to be clearly elucidated. Three investigations (2,3,4) indicate that it is not a simple time- and temperature-dependent phenomenon. Crystalline cobalt exists as pure β-phase above 700°K whereas mixtures of alpha and beta cobalt commonly coexist in varying proportions below this temperature. The values of T_c^o and ΔH_t^o are those selected by Hultgren et al. (1).

Melting Data

The temperature and heat of melting are those selected by Hultgren et al. (1).

Heat of Sublimation

The heat of sublimation is calculated from the data of Edwards et al. (5). See Co(g) table for details.

Sept. 30, 1967

Co

$$\Delta H_f^{298.15} = 4.303 \pm 0.1 \text{ kcal/mol}$$

$$\Delta H_m^\circ = 3.87 \pm 0.06 \text{ kcal/mol}$$

$$\Delta H_v^\circ = 89.219 \text{ kcal/mol}$$

$$S_{298.15}^\circ = 9.79 \text{ gibbs/mol}$$

$$T_m = 1768^\circ\text{K}$$

$$T_b = 3170.29^\circ\text{K}$$

Heat of Formation

The heat of formation (ΔH_f°) of Co(l) is obtained from that of the crystal by adding ΔH_m° and the differences between $H_{1768}^\circ - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity of Co(l) selected by Hultgren et al. (1) is used at temperatures above 1768°K. The heat capacities at temperatures below the melting point are estimated by assuming a glass transition at 1100°K and heat capacities similar to those of the crystal below 1100°K.

Melting Data

See Co(c) table for details.

Vaporization Data

The boiling point is calculated from the adopted thermodynamic functions and the chosen heat of sublimation at 298°K so that the free energy functions calculated by integration of the crystal liquid data and by statistical methods from the gas phase are equal at the boiling point.

Heat of Formation

The heat of formation is the heat of sublimation at 298°K. The adopted value is that reported by Edwards et al. (1). Their value is used because their vapor pressure measurements for Fe (1) and Cu (2) have proved to be very reliable. The results obtained by Vintaikin and Tomash (3) are rejected because their vapor pressure data for Fe (4) resulted in a value for the heat of sublimation which was higher than the accepted value (see JANAF Fe(4) Table for details). The remaining vapor pressure data are rejected either because the drift was too large or because there were not enough points. Second and third law analyses of the available vapor pressure data gave the following results, with reaction A corresponding to $\text{Co}(c) = \text{Co}(g)$ and reaction B corresponding to $\text{Co}(l) = \text{Co}(g)$.

Source	Reaction	Method	No. Pts.	Range, T°K	$\Delta H^{\circ}_{298.15}$	2nd Law	3rd Law	Drift, eu	ΔH°_{298}
Edwards (1)	A	Langmuir	9	1363-1522	101.0 ± 1.0	101.54	101.54	+0.4 ± 0.7	101.54
Kornev (5)	A	Knudsen	8*	1373-1523	98.8 ± 0.8	95.37	95.37	-2.4 ± 0.6	95.37
Dancy (6)	B	Langmuir	1	1823	--	90.61	90.61	--	94.82

*One point rejected due to failure of a statistical test.

**Calculation based on third law ΔH°_{298} .

Heat Capacity and Entropy

The electronic levels are taken from Moore (10). Levels above 25,000 cm⁻¹ are averaged. Unobserved levels below 20,000 cm⁻¹ are estimated.

Heat of Formation

The heat of formation, ΔH_f° , is calculated from the equation $\text{Co}(g) \rightarrow e^- + \text{Co}^+(g)$ with the JANAF auxiliary value for $\text{Co}(g)$; using an ionization potential of 6348 cm⁻¹ (181.377 kcal/mol) obtained from C. E. Moore, "Atomic Energy Levels," Vol. II, U. S. Natl. Bur. Std. Circ. 467, 1949. The value of $H^\circ - H^\circ_{298}$ is -1.504 kcal/mol.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, loc. cit. Levels above 30,000 cm⁻¹ are averaged.

Heat of Formation

Heus and Egan (1) measured the electromotive force of a solid state galvanic cell which involved the reactions

$$E_{973} = 1.611 \text{ volts}$$

$$E_{973} = 2.231 \text{ volts}$$

Combining these results with auxiliary thermodynamic data (2) for the reactants and products, we derive $\Delta H_f^\circ(\text{CoF}_2, \text{c}) = -160.2$ and -159.5 kcal/mol .

Several equilibrium studies (3, 4, 5) involving CoF₂(c) have been reported in the literature. Second and third law analyses of these equilibrium data are summarized below, auxiliary data for Co(c) and CoCl₂(c) are from (6).

Reference	Chemical Reaction	Temp. Range °K	Points	ΔH_{298}° kcal/mol	2nd law gibbs/mol	3rd law gibbs/mol	Drift kcal/mol	$\Delta H_f^\circ(\text{CoF}_{2.1}\text{c})$ kcal/mol
(3)	CoF ₂ (c) + 2HCl(g) \rightleftharpoons CoCl ₂ (c) + 2HF(g)	588-805	3	4.1	1.75±0.4	-1.7±0.1	-162.6±2.0	
(4)	CoF ₂ (c) + H ₂ (g) \rightleftharpoons Co(c) + 2HF(g)	673-873	3	35.2	31.5±1.0	-4.2±3.5	-161.8±2.0	
(5)	CoF ₂ (c) + H ₂ O(g) \rightleftharpoons CoO(c) + 2HF(g)	773-1023	5	30.2	31.1±0.2	0.8±0.3	-160.4±2.0	

*Third law values except for the first reaction.

We note that Heus and Egan (1), in the same paper, measured $\Delta H_{298}^\circ(\text{AlF}_3, \text{c}) = -360.2 \text{ kcal}$ in excellent agreement with the JANAF value (2). Domange (5) also measured similar equilibria for MgF₂ and CaF₂, which were very consistent with the JANAF heats of formation (2). Jellinek and Rudat (4) reported similar equilibria for PbF₂(c), which show excellent consistency with the JANAF heat of formation (2). Thus, it is apparent that these three sets are probably quite reliable, and we adopt $\Delta H_{298.15}^\circ(\text{CoF}_2, \text{c}) = -160.5 \pm 1 \text{ kcal/mol}$.

Heat Capacity and Entropy

Catalano and Stout (7) measured low temperature heat capacities in the temperature range 10° to 300°K. Heat capacity data above 300°K are calculated from the high temperature (468-1400°K) enthalpy data of Binford et al. (8). Both sets of data were smoothed by computer and joined at 298.15°K.

The value of $S_{298.15}^\circ$ is obtained from the low temperature heat capacity data of Catalano and Stout (7) and is based on $S_{10}^\circ = 0.013 \text{ gibbs/mol}$.

Melting Data

$T_m = 1400^\circ\text{K}$ is from the high temperature enthalpy studies of Binford et al. (8). ΔH_m is calculated from their enthalpy data. Premelting of the sample is assumed to be responsible for the rapid rise in the enthalpy near the melting point. This enthalpy is included in ΔH_m .

Heat of Sublimation

Kana'an et al. (9) made sublimation studies of CoF₂ using Knudsen and Langmuir techniques over the temperature range 972°-1241°K. Second and third law analyses of these sublimation pressures are summarized below.

Method	Temp. Range °K	No. of Points	ΔH_{298}° kcal/mol	Drift gibbs/mol
Knudsen	1058-1242	17	75.0	75.1±0.1
Langmuir	972-1032	8	72.8	75.5±0.2

The selected value is $\Delta H_{298}^\circ = 75.3 \pm 3.0 \text{ kcal/mol}$.

Cobalt Difluoride (CoF₂)

(Liquid)

GFW = 96.9300

COBALT DIFLUORIDE (CoF₂)

(LIQUID)

GFW = 96.9300

$$S_{298.15}^{\circ} = 20.61 \pm 2.5 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = -152.412 \pm 4.0 \text{ kcal/mol}$$

$$T_m = 1400^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 14.058 \pm 3.0 \text{ kcal/mol}$$

$$T_b = 12012^{\circ}\text{K}$$

$$\Delta H_v^{\circ} = [48.0] \text{ kcal/mol}$$

Heat of Formation

$\Delta H_f^{\circ}(l)$ is calculated from $\Delta H_f^{\circ}(c)$ by adding the heat of melting and the difference in ($H_{1400-H_{298}}$) between the crystal and liquid.

Heat Capacity and Entropy

The heat capacity of liquid CoF₂ is estimated by comparison with those for FeCl₂(l), MgF₂(l), and PbF₂(l) and is assumed constant in the temperature range 298°-3000°K. Binford et al. (1) reported $C_p = 30.3$ gibbs/mol for liquid CoF₂ at 1444°K. This value is based on only two enthalpy points near the melting point and appears high in comparison with heat capacities for other liquid metal dihalides. Therefore, the value is not adopted.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the CoF₂(c) table for details.

Vaporization Data

T_b is the temperature at which the Gibbs energy change for the process CoF₂(l) + CoF₂(g) approaches zero. The difference between the heat of formation of the gas and liquid at T_b is ΔH_v° .

Bond Distance: Co-F = [1.72] Å
Bond Angle: F-Co-F = [165°]
Product of Moments of Inertia: $I_{AB}I_C = 6.5424 \times 10^{-116} \text{ g}^3 \text{ cm}^6$ $\sigma = 2$

Heat of Formation

The heat of formation of gaseous CoF_2 , $\Delta H_f^\circ = -88.1 \pm 7.0$ kcal/mol, is calculated from the heat of formation of the crystal, $\Delta H_{298}^\circ = -163.4 \pm 4.0$ kcal/mol, and the heat of sublimation, $\Delta H_{298}^\circ = 75.3 \pm 3.0$ kcal/mol. The sublimation value is determined from a third law analysis of the vapor pressure data for CoF_2 reported by Kana'an et al. (1). See $\text{CoF}_2(\text{c})$ table for details.

Heat Capacity and Entropy

Büchler et al. (2) investigated the deflection of a molecular beam of $\text{CoF}_2(\text{g})$ by an electric field and found that within the sensitivity of the apparatus the molecule was nonpolar and consequently possessed a linear structure. Hartie et al. (3) recently investigated the infrared absorption spectra of several transition metal difluorides through the use of matrix isolation techniques. Isotopic shift measurements for matrix isolated NiF_2 , ZnF_2 , and CuF_2 in neon and argon indicated that these species were slightly bent. Based upon these results, the authors estimated the F-Co-F angle as 165° . This value is adopted here. The bond length was estimated by Brewer et al. (4). Individual moments of inertia are $I_A = 0.1925 \times 10^{-39}$, $I_B = 18.341 \times 10^{-39}$, and $I_C = 18.533 \times 10^{-39} \text{ g cm}^2$.
Hartie et al. (3) isolated CoF_2 in neon and argon matrices and observed the ν_3 fundamental at 762 cm^{-1} . They also calculated $\nu_1 = 600 \text{ cm}^{-1}$ by a valence force field method and estimated ν_2 as 151 cm^{-1} by applying the variation in the frequencies for the chlorides of Co, Ni, Cu, and Zn to the fluorides. The electronic levels and quantum weights are estimated by comparison with the electronic energy levels for $\text{Co}^{2+}(\text{g})$ ion (5) and those for $\text{CoF}_2(\text{g})$ observed by Hough et al. (6).

 $\Delta H_m^\circ = 0.499 \pm 0.001 \text{ kcal/mol}$
 $\Delta H_m^\circ_{298.15} = 18.32 \text{ kcal/mol}$

$S^\circ_{298.15} = 20.351 \pm 0.05 \text{ gibbs/mol}$
 $T_m = 301.55 \pm 0.01^\circ\text{K}$

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacities, 0.19-301.55°K, have been measured by Dauphinee (1), McCollum (2), Martin (3), Lien (4), Filby (5), and Morgan (6). The adopted values are derived based on the Cp data reported by Filby (5) and Lien (4). Lien measured the heat capacities in the temperature range 0.1874 to 1.20°K in the adiabatic demagnetization cryostat and at higher temperatures, 1.2 to 4.09°K, in the liquid-helium temperature cryostat. The Cs sample was obtained from a commercial source of 99.8 per cent purity. Filby determined the Cp values in the temperature ranges 0.4-1.5°K, 3-26°K and 20-320°K, using commercial samples of 99.9 per cent purity. These two sets of measurements are joined smoothly at 4°K. $S^\circ_{298.15}$ is derived from the adopted heat capacities, based on $S^\circ_{0.20} = 0.0002 \text{ eu}$.

Dauphinee (1) determined the heat capacities of Cs(c) employing a sample badly contaminated with oxygen. In the temperature range of approximately 100 to 200°K, an anomaly of Cp curve somewhat similar to those found for sodium and potassium was reported. This anomaly was not observed by Filby who used the higher purity cesium sample. The Cp values reported by Dauphinee are lower than the adopted ones by about 0.5 to 1.5 per cent in the temperatures 55 to 220°K; above 270°K his reported heat capacities are unreasonably high. Therefore the data are not adopted for evaluation. McCollum (2) calculated the Debye θ values from the measured low temperature heat capacities and plotted them, since no numerical data were reported these were not used. The low temperature Cp values determined by Martin (3) and Morgan (6) are in good agreement with the adopted ones.

Melting Data

See Cs(l) table for details.

Heat of Sublimation

 $\Delta H_m^\circ_{298.15}$ is calculated as the difference between $\Delta H_f^\circ_{298.15}$ for Cs(g) and Cs(c).

S°_{298.15} = 22.005 gibbs/molT_m = 301.55 ± 0.01°KT_b = 951.6°KΔH_f°_{298.15} = 0.499 kcal/molΔH_m° = 0.499 ± 0.001 kcal/molΔH_v° = 16.198 kcal/mol

Heat of Formation

The heat of formation is obtained from ΔH_f°₂₉₈(c) by adding ΔH_m° and the difference between H°_{301.55} - H°₂₉₈ for Cs(l) and Cs(s).

Heat Capacity and Entropy

The enthalpies of Cs(l) have been measured by Tepper et al. (1), Achener (2), and Lemmon et al. (3), using drop calorimetry. Lemmon et al. used a cesium sample of 99.994 per cent purity and encapsulated in Nb-12p alloy. They found that Cs(l) does not behave as a normal liquid from about 100-300°C. The thermal conductivity measurements of Cs(l) show a change of slope at about 200°C and its electrical resistivity also shows scatter in this region. The heat capacities, 301.55-1435.2°K, derived from the reported enthalpies (corrected for vapor condensation), are consistent with the low temperature heat capacity data on Cs(c) at 298°K and are adopted.

Tepper et al. measured the enthalpies in the temperature range 351.1-1228°K. The reported enthalpy values are considerably higher, over 20 per cent, at the lower end of the measured temperature range than the adopted ones. However, the agreement becomes better at the higher temperature end. Achener determined the enthalpies of Cs(l) at the temperatures 340.1-1175.7°K. Using the reported enthalpies, the average heat capacity is derived to be 8.75 gibbs/mol, which is unreasonably high by comparison with those for the other alkali metals. The above two sets of data are not used for evaluation. The enthalpies of Cs(l), 773-1423°K, were also measured by Shapiro (4) and quoted by (3). The derived constant heat capacity, 7.60 gibbs/mol, is in reasonable agreement with the adopted ones.

Heat capacities of Cs(l), 301.55-373.2°K, were reported by Filby (5), 301.55-320°K, Dauphinee (6), 310-320°K, and Rengade (7), 301.7-373.2°K. The values obtained are consistent with the adopted ones.

S°_{298.15} is derived in a manner analogous to that of the heat of formation.

Melting Data

The melting point and heat of melting have been determined by many investigators. The results reported are presented in the table below. The adopted T_m and ΔH_m° are obtained from (5). The two determinations of fraction melted against temperature are in very good agreement with one another and lead to a linear plot of reciprocal fraction melted against temperature thus indicating that the major impurity is solid insoluble. This is confirmed by a graph of excess heat capacity against the reciprocal of (T₀-T), where T₀ is the melting point, which indicates an impurity (mainly oxygen) concentration of 0.06 atomic per cent.

Vaporization Data

T_b is the temperature at which the Gibbs energy change (ΔG°) for the reaction Cs(l) = Cs(g) approaches zero. The difference between ΔH_f°(Cs, g) and ΔH_f°(Cs, l) at T_b is ΔH_v°. Due to the presence of dimer (Cs₂) in the vapor (see Cs(g) and Cs₂(g) tables for details), the real boiling point of Cs(l) is calculated to be 941.3°K at which the vapor mixture contains 0.835 mol of monomer/mol of Cs(l) vaporized, or 9.0 per cent of dimer. The corresponding heat of vaporization is evaluated as 15.26 kcal/mol of vapor mixture.

Heat of Formation

The total pressures of Cs(g) and Cs₂(g) over Cs(l) in the temperature range 738.6 to 1268.3°K have been measured, using the boiling point method, by Bonilla (4), Tepper (3) and Achener (2); using the static method, by Kröner (10), Scott (7) and Stone (11); and the positive ion method by Taylor (6). Fichtbauer (8) and Hacksapill (9) have determined the vapor pressures of Cs(l) by a spectroscopic method and P-V-T relationships, respectively. Based on the reported total pressures, the partial pressures of Cs(g) and Cs₂(g) are evaluated by use of dimer-monomer ratios calculated from JANAF free energy functions and $\Delta H^{\circ}_{298.15} = 11.24$ kcal/mol for the reaction $Cs_2(g) = 2Cs(g)$. The value of $\Delta H^{\circ}_{298.15}$ is adopted such that the derived monomer partial pressures give consistent second and third law heats of vaporization. The results are presented in the table below.

Stone et al. (1) measured the vapor pressures of Cs(l) at temperatures 920-1682°K and pressures 0.811-33.53 atm in both the saturation and superheat regions, using a static method and a refractory metal apparatus with a diaphragm as a null-point detector. These vapor pressures reported at temperatures 920-1267.3°K and total pressure below 10 atm are used for evaluation and are reasonably represented by a mixture of monomer and dimer ideal gases. The value of ΔH°_{298} (Cs, g) is adopted as 18.3240.5 kcal/mol which is derived based on the vapor pressures reported by Stone et al. The results obtained are in reasonable agreement with the values derived from the other vapor pressure sets.

*Calculation based on the third law ΔH°_{298} and $\Delta H^{\circ}_{298} = 0$ and 0.499 kcal/mol for Cs(l) and Cs(g), respectively.

Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights ($n \leq 10$) are obtained from Moore (11). The electronic levels above 25000 cm⁻¹ are average values calculated from those given by Moore. The missing electronic levels, where quantum number $n = 7, 8, 9$ and 10, and the corresponding quantum weights are estimated according to the method recommended by Gurvich (12). The calculated values at 6000°K, e.g. Cp = 19.668 gibbs/mol and S° = 61.980 eu, are not significantly different from the corresponding values, Cp = 19.650 gibbs/mol and S° = 61.871 eu, obtained from using all the electronic levels reported by Moore for calculation without cutting or adding any levels.

Cs⁺Ground State Configuration ¹S₀S[°]_{298.15} = 40.565 ± 0.0005 gibbs/molΔH[°]_f = 108.5 ± 1 kcal/molΔH[°]_{f,298.15} = 108.1 ± 1 kcal/mol

Electronic Levels and Quantum Weights

$$\frac{g_i, \text{cm}^{-1}}{0} \frac{g_i}{1}$$

Heat of Formation

The ionization potential of Cs(g) was reported as 3.893 eV or 89.776 kcal/mol by C. E. Moore, U. S. Natl. Bur. Std. Circ. 467, 1958. Based on this data we derived ΔH[°]_{f,298.15} = 108.1 ± 1 kcal/mol for Cs⁺(g).

Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights were reported by Moore, loc. cit. However, the lowest electronic level above ground state is given as 107392.33 cm⁻¹ which is so high that the evaluated thermodynamic properties of Cs⁺(g) will not be affected if we disregard all of these higher levels for calculation. Therefore we do not use them. The H[°]₂₉₈ value at 0°K is -1.481 kcal/mol.

(CRYSTAL)

GFW = 151.9034

 $\Delta H^\circ_f = \text{Unknown}$ $\Delta H^\circ_{298,15} = -132.57 \pm 0.5 \text{ kcal/mol}$ $\Delta H_m^\circ = 5.19 \text{ kcal/mol}$ $\Delta H^\circ_{298,15}(\text{to monomer}) = 47.37 \text{ kcal/mol}$ $S^\circ_{298,15} = [21.1 \pm 2] \text{ gibbs/mol}$ $T_m = 976^\circ\text{K}$

Heat of Formation

The enthalpy of solution (ΔH_{soln}) of CsF(c) in water at 298.15°K has been carefully determined with an adiabatic calorimeter by Somsen (1). Based on the reported value, $\Delta H_{\text{soln},298} = -8.62 \pm 0.04 \text{ kcal/mol}$ and $\Delta H^\circ_{298} = -61.69$ (2) and -79.5 kcal/mol (3) for Cs⁺(aq, H₂O) and F⁻(aq, H₂O), respectively, the heat of formation for CsF(c) is calculated to be -132.57 kcal/mol which is adopted. The value, $\Delta H_{\text{soln},298} = -8.81 \pm 0.2 \text{ kcal/mol}$ for CsF(c), was reported by Parker (1), which is in agreement with the value measured by Somsen (1).

Heat Capacity and Entropy

The heat capacities of CsF(c) are estimated according to the method of Kristov (5), based on $H^\circ_{298} - H^\circ_{298} = 9.4 \text{ kcal/mol}$ reported by Dworin (6). The entropy (S°_{298}) is estimated such that the calculated and observed vapor pressures are in good agreement (see CsF(g) and Cs₂F₂(g) tables for details).

Melting Data

T_m and ΔH_m° are obtained from Bredig (7) and Dworin (8). Bukhalova (9) reported $T_m = 958^\circ\text{K}$, which is not adopted.

Heat of Sublimation

ΔH°_{298} is calculated as the difference between ΔH°_{298} for CsF(g) and CsF(c).

CsF

CESIUM FLUORIDE (CsF)

(LIQUID)

GFW = 151.9034

 $S_{298.15}^{\circ} = [21.534] \text{ gibbs/mol}$ $\Delta H_f^{\circ} 298.15 = -129.983 \text{ kcal/mol}$ $\Delta H_m^{\circ} = 5.19 \text{ kcal/mol}$ $\Delta H_v^{\circ} = 27.6 \text{ kcal/mol of liquid}$ $T_m = 976^{\circ}\text{K}$ $T_b = 1504^{\circ}\text{K}$

Heat of Formation

 $\Delta H_f^{\circ} 298(4)$ is obtained from $\Delta H_f^{\circ} 298(c)$ by adding ΔH_m° and the difference between H_{298}° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

Dorbin (1) measured the heat capacity of CsF(l) at the melting point to be 17.7 gibbs/mol which is adopted and assumed to be constant in the temperature range 298 - 3000°K. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See CsF(c) for details.

Vaporization Data

T_b is the temperature at which the calculated vapor pressures of CsF(g) and Cs₂F₂(g) equal one atmosphere. The vapor composition at T_m is calculated as CsF 80.3 per cent and Cs₂F₂ 19.7 per cent. The heat required to vaporize one mole of liquid to the above vapor mixture at T_m is ΔH_v° .

T_b has been observed as 1524 and 1526°K by Wartenberg (1) and Ruff (2), respectively, which are in fair agreement with the calculated one, 1504°K.

Heat of Formation

The vapor pressures of CsF(c) and CsF(g) were measured by the manometric method (A) by Martenberg (1), Ruff (2) and Cantor (3); the torsion-fiber effusion method (B) by Pugh (4); and the Knudsen effusion method (C) by Scheer (5). Based on the reported total pressures, the corresponding partial pressures of CsF(g) and Cs₂F₂(g) were evaluated using the adjusted heats of vaporization and Gibbs free energy functions such that the calculated and observed total pressures are in reasonable agreement, and the derived enthalpy changes by the second and third law methods are consistent. The results obtained are presented in the table below. The value of ΔH°₂₉₈ (CsF, g) is adopted as -82.5 ± 0.5 kcal/mol.

The dissociation energy (D₀) of CsF(g) has been reported using the spectroscopic convergence limit as 5.65 eV (130.3 kcal/mol) and 5.56 eV (126.8 kcal/mol) by Herzberg (6) and Gaydon (7), respectively. Based on the above two D₀ values, and ΔH°₀ = 18.68 and 18.36 for Cs(g) and F(g), we obtain the corresponding value for ΔH°₂₉₈ (CsF, g) as -93.85 and -90.39 kcal/mol, which are not adopted.

Investigator	Reaction*	Method	ΔH° ₂₉₈ , kcal/mol	Drift eu	ΔH° ₂₉₈ , kcal/mol**
1. Martenberg (1921)	2	A	45.39±0.15	44.98	-0.28±0.10
2. Ruff (1922)	2	A	44.78±1.70	44.94	-0.11±1.18
3. Cantor (1958)	2	A	44.83	44.89	0.05±0.04
4. Pugh (1958)	1	B	48.52±0.03	47.57	-1.18±0.04
5. Scheer (1962)	1	C	48.43±0.27	46.61	-2.35±0.35

*1 represents the reaction CsF(c) = CsF(g); 2, the reaction CsF(l) = CsF(g).

**Calculation based on the third law ΔH°₂₉₈ and ΔH°₂₉₈ = -132.57 and -129.983 kcal/mol for CsF(c) and CsF(l), respectively.

Heat Capacity and Entropy

The ground state configuration was reported by Herzberg (6). The molecular constants are obtained from Honig (2), who observed the microwave spectra of CsF(g) at temperatures of about 700°C. Based on the J = 1 + 2 transition, the molecular constants are derived. The vibrational frequency (ω_e) has been reported, from different kinds of spectra, in the range 270 - 385 cm⁻¹ by many investigators, e.g., radiofrequency, infrared, ultraviolet, microwave, etc. The value of ω_e adopted was reported by Balikov (8), who also reviewed the ω_e values obtained by the earlier investigators.

CsF

GFW = 148.9044

(IDEAL GAS)

CESIUM MONOXIDE (CsO)

Ground State Configuration $[2^1P_1]$ $\Delta H_f^\circ = [15.5 \pm 10] \text{ kcal/mol}$ $\Delta H_f^{*298.15} = [15.0 \pm 10] \text{ kcal/mol}$ $S_{298.15}^\circ = [61 \pm 1] \text{ gibbs/mol}$

Electronic Levels and Quantum Heights

$$\frac{e_1, \text{ cm}^{-1}}{0} = \frac{g_1}{[4]}$$

$$\omega_e = [280] \text{ cm}^{-1} \quad \sigma = 1$$

$$B_e = [0.199] \text{ cm}^{-1} \quad \alpha_e = [0.001] \text{ cm}^{-1}$$

$$r_e = [2.40] \text{ \AA}$$

Heat of Formation

The heat of formation is estimated from three calculated values. The methods of estimation are described as follows. Brewer and Margrave (1) suggested that the ΔH_f value for HO(g) from the gaseous ions can be taken as the mean of the corresponding ΔH_f values for the alkali fluoride and chloride with a maximum uncertainty of 10 kcal/mol. Adopting $\Delta H_f^{*298} = -131.1$ and -109.6 kcal/mol for the reaction $\text{Cs}^+(g) + \text{F}^-(g) = \text{CsF(g)}$ and $\text{Cs}^+(g) + \text{Cl}^-(g) = \text{CsCl(g)}$, respectively, we obtain $\Delta H_f^{*298} = -120.4$ kcal/mol for $\text{Cs}^+(g) + \text{O}^-(g) = \text{CsO(g)}$ which leads to $\Delta H_f^{*298}(\text{CsO, g}) = 12.0$ kcal/mol. The ΔH_f^{*298} values of the above species used for calculation are taken from the respective JANAF Thermochemical Tables.

Based on the assumption that $\text{D(Cs-O)} = 1/2[\text{D(Ca}_2\text{)} + \text{D(O}_2\text{)}]$, we derive $D_{298}(\text{Cs-O}) = 85.2$ kcal/mol and $\Delta H_f^{*298} = 12.7$ kcal/mol for CsO(g) .

Adopting the Cs-O bond energy as half of the atomization energy of Cs_2O , we calculate $\text{D(Cs-O)} = 60 \pm 10$ kcal/mol and $\Delta H_f^{*298}(\text{CsO, g}) = 17 \pm 10$ kcal/mol.

The heat of formation for CsO(g) is tentatively selected as 15 ± 10 kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of the isoelectronic molecule OH(g) . ω_e is estimated from those of LiO(g) , CaF(g) , and CsCl(g) . The bond distance is taken from that in CsOH(g) reported by Lide and Kuczkowski (2). ω_e is estimated by comparison with those of the other alkali oxides. The values of B_e and α_e are calculated from r_e , ω_e and ω_e^2 by the method suggested by Herzberg (3). The moment of inertia is $1.413 \times 10^{-38} \text{ g cm}^2$.

Heat of Formation

The vapor pressures of Cs(g) and Cs₂(g) over Cs(l) have been measured by many investigators (see Cs(g) table for details). For internal consistency, the vapor pressures determined at temperatures 980-1684°K and pressures 1.1-7.5 atm by Stone (1) are employed for evaluation. The P-T data on cesium reported by Tepper (2) are employed for comparison. Using the reported pressures, the JANAF free energy functions and ΔHf°₂₉₈ = 11.24 kcal/mol for the reaction Cs₂(g) = 2Cs(g), the equilibrium constants for this reaction are evaluated. From the derived equilibrium constants, the enthalpy change of the reaction Cs₂(g) = 2Cs(g) is calculated by the second and third law methods. The results are presented in the table below. The value of ΔHf°₂₉₈(Cs₂, g) is adopted as 25.40 ± 1.0 kcal/mol. The D₀(Cs-Cs) was reported as 0.45 eV or 10.38 kcal/mol by Gaydon (3) and Herzberg (3), yielding ΔHf°₂₉₈ = 25.93 ± 0.92 kcal/mol for Cs₂(g) which is in agreement with the adopted value, within the experimental uncertainty.

Expt. No.	Points	Temperature, °K	Pressure, atm	ΔHf° ₂₉₈ , kcal/mol	ΔHf° ₂₉₈ , kcal/mol
28 (1)	23	1151-1680	4.7-7.5	12.39±0.10	11.63
30 (1)	24	980-1684	1.1-2.0	10.90±0.16	11.24
38 (1)	19	1100-1657	3.2-5.2	12.28±0.22	11.22
1-6, 8, 10 (2)	54	955-1375	1.0-5.4	12.35±0.70	11.47

*Calculation based on the third law ΔHf°₂₉₈ and ΔHf°₂₉₈(Cs, g) = 18.32 kcal/mol.

Heat Capacity and Entropy

The ground state configuration, electronic levels and quantum weights, ω_e and ω_x, are obtained from Herzberg (3). The second electronic level is reported as 8800-11000 cm⁻¹ and the value 9000 cm⁻¹ is chosen for calculation. The last two electronic states are estimated by comparison with those for K₂(g) given by (3). The bond distance r_e is calculated from ω based on the method suggested by Guggenheimer (4). The values of B_e and α_e are calculated (3). The moment of inertia is 2.2145 x 10⁻³⁷ g cm².

[110] (1)	[220] (1)
[210] (1)	[230] (1)

Bond Angle: Cs-F = (2.35) Å

Bond Distance: F-Cs-F = (85°)

Product of the Moments of Inertia: I_AI_BI_C = {3.126 × 10⁻¹¹²} g³ cm⁶

Heat of Formation

Evidence from the velocity distribution in molecular beams (1) has shown that alkali halide vapors contain significant amounts of polymeric species. Using the same method Eisenstadt (2) determined the molecular composition of CsF vapor in the temperature range 838 - 919°K. Based on the reported equilibrium constants for the reaction (CsF)₂(g) = 2CsF(g), we evaluate the enthalpy change (ΔH_{f,298}^o) by the second and third law methods to be 40.53 ± 1.75 and 42.34 ± 0.26 kcal/mol, respectively. Employing ΔH_{f,298}^o = 42.34 and ΔH_{f,298}^o(CsF, g) = -85.2 kcal/mol, we obtained ΔH_{f,298}^o = -212.74 kcal/mol for Cs₂F₂(g), which is adopted.

Heat Capacity and Entropy

The Cs₂F₂ molecule is assumed to have a rhombic configuration of symmetry D_{2h} as Cs₂Cl₂(3). The Cs-F bond distance is taken as the same as that in CsF(g). The bond angles and vibrational frequencies are estimated by comparison with those of other dimeric alkali halides (3, 4). The three principal moments of inertia are: I_A = 1.590 × 10⁻³⁸, I_B = 1.325 × 10⁻³⁷ and I_C = 1.484 × 10⁻³⁷ g cm².

$$\Delta H_m^\circ = 3.17 \pm 0.15 \text{ kcal. mole}^{-1}$$

$$\Delta H_g^\circ 298.15 = 81 \pm 0.4 \text{ kcal. mole}^{-1}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The low temperature specific heat of copper has been measured by several workers and generally there is good agreement. The selected values lie close to the determinations of J. A. Kok and W. H. Keesom (1.2-20°K), Physica 3, 1035 (1936); D. L. Martin (20-300°K), Can. J. Phys. 38, 17 (1960); C. B. Satterthwaite, R. S. Creig and W. E. Wallace, J. Am. Chem. Soc. 76, 232 (1954), and S. M. Dookerty, Can. J. Research 2, 84 (1933) and 15B, 59 (1937). Several other workers have reported values of C_p slightly higher than the adopted values especially W. F. Glaue and P. F. Heads, J. Am. Chem. Soc. 63, 1897 (1941), however these measurements were not used for reasons discussed by Martin. The heat capacity above room temperature has been determined directly by several workers, the values of R. E. Pawel and E. E. Stansbury, J. Phys. Chem. Solids 26, 607 (1965) join well with the low temperature data and are adopted. These values lie within 1% of the values adopted by R. Hultgren, R. L. Orr, P. D. Anderson, and K. K. Kelley "Selected Values of Thermodynamic Properties of Metals and Alloys", John Wiley and Sons, Inc., New York, 1963. Several determinations of the solid enthalpy are also in good agreement with selected heat capacity curve. For references to these determinations refer to Hultgren et al. loc. cit.

Melting Data.

The melting point of copper is well established and the recent determination of W. Heyne, Exptl. Tech. Physik. 12, 87 (1964) is adopted. The heat of fusion was obtained from the calculated enthalpy of the solid at the melting point and the liquid enthalpy measurements of F. Wust, A. Meuthen and R. Durrer, Forsch. Geb. Ingenieurw. VDI-Forsch. 204 (1918). The liquid enthalpies of I. B. Fieldhouse, J. C. Hedge, J. I. Lang and T. E. Waterman, ASTIA Doc. No. A. D. 150954 are somewhat higher than the adopted values.

Sublimation Data.

See Cu(g) for details.

Dec. 31, 1965

COPPER (Cu)

(LIQUID)

At. Wt. = 63.54

$$\Delta H_f^0 = 8.663 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^0 = 298.15 = 2.224 \text{ kcal. mole}^{-1}$$

$$\eta_m^0 = 1356.6^\circ \text{K.}$$

$$\Delta H_m^0 = 3.17 \pm 0.15 \text{ kcal. mole}^{-1}$$

$$\eta_b^0 = 2848^\circ \text{K.}$$

$$\Delta H_b^0 = 72.743 \text{ kcal. mole}^{-1}$$

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH_m^0 and the difference between $H_{1356.6}^0 - H_{298}^0$ for (c) and (l).

Heat Capacity and Entropy.

The heat capacity was calculated from the enthalpy data of P. Kist, A. Mathen and R. Durrer, Forsch. Geb. Ingenieurw. VDI-Forsch. 204 (1916). The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

See crystal table for details.

Vaporization Data.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

Heat of Formation.

The heat of sublimation has been determined by second and third law analysis of the vapor pressure data of a large number of investigators. The results are summarized below:

Ref.	Range ^a , K.	Method	Points	$\Delta H_{\text{subl.}}^\circ 298.15 \text{ kcal. mole}^{-1}$	3rd law	Drift
1.	1242-1340	Knudsen	6	80.6 \pm 0.2	81.39 \pm 0.04	0.3 \pm 0.2
2.	1347-1523	Knudsen	18*	80.6 \pm 0.6	80.22 \pm 0.3	-1.9 \pm 0.2

The first eight references may be considered to have reasonable drifts and second and third law agreement. The three Langmuir values are grouped closely together at about 80.3 kcal. mole⁻¹. The Knudsen values all lie a little higher averaging 81.4 kcal. mole⁻¹, the single transport determination is at 80.55 kcal. mole⁻¹. If the evaporation coefficient is not unity in the Langmuir experiments then one would observe lower pressures and higher heats of sublimation, thus it appears that the coefficient must be unity and that all techniques are measuring valid heats of sublimation. A value of 81 \pm 0.5 kcal. mole⁻¹ has been chosen weighted toward the more precise Knudsen work of Herzog.

Heat Capacity and Entropy.

The electronic ground state configuration and higher electronic levels were taken from C. E. Moore "Atomic Energy Levels", Natl. Bur. Stds. Circular 467, Washington 1952.

23998.3	3	88505.7	9
26264.5	5	95565.7	9

Heat of Formation.

The heat of formation was obtained from the dissociation limit of Cu(g) which was given as 6237.2 cm.⁻¹ (or 178.187 kcal. mole⁻¹) by C. E. Moore "Atomic Energy Levels", Nat. Bur. Stds. Circ. 467, Washington 1952. This value applies to 0°K. the enthalpy of Cu, Cu⁺ and e⁻ between 298°K. and zero are all 1.481 kcal. mole⁻¹, thus at 298°K. the dissociation energy is 179.668 kcal. mole⁻¹. The heat of formation was then obtained from the reaction Cu(g) → Cu⁺ + e⁻ as ΔH_f⁰ 298.15 = 260.668 ± 0.5 kcal. mole⁻¹, the uncertainty is that due to Cu(g).

Heat Capacity and Entropy.

The ground state configuration and higher electronic levels were taken from C. E. Moore, loc. cit. Levels above 100,000 cm.⁻¹ were not included since they do not affect the thermodynamic function, levels above 30,000 cm.⁻¹ were averaged.

COPPER MONOFLUORIDE (CuF)

(CRYSTAL)

GFW = 82.5384

ΔH_{f,0}^o = UnknownS_{298,15}^o = [15.5 ± 0.5] gibbs/molT_m = UnknownΔH_{f,0}^o = UnknownΔH_{f,298,15}^o = [-46 ± 10] kcal/molΔH_{f,298,15}^o = [58] kcal/mol

Heat of Formation.

The heat of formation (ΔH_{f,298,15}^o) for CuF(c) is not available from literature at the present time. The lattice energy (U_o) for CuF(c) has been calculated to be 209, 213 and 232 kcal/mol, based on the assumption of ionic bonding in CuF(c), by Pauling, Zachariasen and Ebert and Kottinek, respectively (see T. C. Haddington, Trans. Faraday Soc. 55, 1531 (1959) for details). The corresponding enthalpy change for the reaction CuF(c) = Cu⁺(g) + F⁻(g) was evaluated as 210.18, 214.18 and 235.18 kcal/mol. Using ΔH_{f,298,15}^o = 280.67 kcal/mol for Cu⁺(g) and -62.2 kcal/mol for F⁻(g), the values of ΔH_{f,298,15}^o (CuF, c) were calculated to be -11.7, -15.7 and -34.7 kcal/mol. However, based on ΔH_{f,298,15}^o(CuF, g) = 12 ± 9 kcal/mol which was measured, the values of ΔH_{f,298,15}^o would be 23.7, 27.7 and 46.7 kcal/mol which seem to be too small. By comparison with those for KF(c) and HgF(c), the value of ΔH_{f,298,15}^o was estimated as 58 kcal/mol. From this ΔH_{f,298,15}^o value and ΔH_{f,298,15}^o (CuF, g), the heat of formation for CuF(c) was derived.

Heat Capacity and Entropy.

The heat capacities, 298.15-1000°K, and S_{298,15}^o were estimated by comparison with those for CuCl(c), NaCl(c) and NaF(c). The Cp values above 1000°K were obtained by graphical extrapolation.

Heat of Sublimation.

The value of ΔH_{f,298,15}^o was estimated by comparison with those for KF(c) and HgF(c).

COPPER MONOFLUORIDE (CuF)

(IDEAL GAS)

OFW = 82.5384

Ground State Configuration $1\Sigma^+$

$\Delta H_f^\circ = 12 \pm 9 \text{ kcal/mol}$

$S_{298.15}^\circ = 54.11 \text{ gibbs/mol}$

$\Delta H_f^\circ_{298.15} = 12 \pm 9 \text{ kcal/mol}$

Electronic Levels and Quantum Weights

$$\frac{\epsilon_f, \text{cm}^{-1}}{0} = \frac{g_f}{1}$$

$$\omega_e x_e = 3.941 \text{ cm}^{-1}$$

$$\alpha_e = 0.004596 \text{ cm}^{-1}$$

$$B_e = 0.3794 \text{ cm}^{-1}$$

$$r_e = 1.743 \text{ \AA}$$

Heat of Formation

Based on spectroscopic data, the dissociation energy (D_0°) of CuF (g) was selected as $3.0 \pm 1.0 \text{ eV}$ by A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953. Using $\Delta H_f^\circ_{298.15} = 18.36$ and 80.71 kcal/mol for F(g) and Cu(g), respectively, the value of $\Delta H_f^\circ_{298.15}$ for CuF (g) was calculated to be $30 \pm 23 \text{ kcal/mol}$.

Values of the dissociation energy for CuF(g) have been derived by R. A. Kent, J. D. McDonald, and J. L. Margrave, J. Phys. Chem. **70**, 874 (1966), as 3.63 ± 0.2 to $4.1 \pm 0.5 \text{ eV}$, based on mass spectrometric studies of CuF₂ sublimation from a Knudsen cell, the appearance potential of CuF⁺ ion from CuF₂ in both reducing and nonreducing systems, and a theoretical calculation assuming an ionic model like that used by E. S. Rittner, J. Chem. Phys. **19**, 1030 (1951). Until further data are available, a value $D(\text{CuF}) = 3.8 \pm 0.5 \text{ eV}$ was recommended. Using this dissociation energy for CuF (g), the heat of formation (298.15°K) for CuF(g) was evaluated to be $12 \pm 9 \text{ kcal/mol}$ which is adopted here.

Heat Capacity and Entropy

The values of ground state configuration, ω_e , $\omega_e x_e$, B_e , α_e and r_e were obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., New York, 1950, and corrected to the average isotopic species.

CuF₂COPPER DIFLUORIDE (CuF₂) (CRYSTAL)

OFW = 101.5368

$\Delta H_f^\circ = \text{Unknown}$
 $\Delta H_f^\circ_{298.15} = -131.2 \pm 0.8 \text{ kcal/mol}$
 $\Delta H_m^\circ = [9.4] \text{ kcal/mol}$
 $\Delta H_f^\circ_{298.15} = 82.5 \pm 0.6 \text{ kcal/mol}$
 $T_m = 1043^\circ\text{K}$

Heat of Formation.

The chemical equilibrium for the reaction (1) $\text{CuF}_2(\text{c}) + \text{H}_2(\text{g}) = \text{Cu}(\text{c}) + 2\text{HF}(\text{g})$ has been studied by K. Jellinek and A. Rudet, Z. anorg. allgem. Chem. 175, 281 (1928). The equilibrium gas phase composition was found to be HF 4.3% and H₂ 95.7%, at 423°K. From this data the enthalpy change ($\Delta H^\circ_{298.15}$) of the reaction was evaluated. The equilibrium for the reaction (2) $\text{CuF}_2(\text{c}) + \text{H}_2\text{O}(\text{g}) = \text{CuO}(\text{c}) + 2\text{HF}(\text{g})$ was investigated by L. Donange, Compt. rend. 200, 239 (1935). Based on the equilibrium data reported, the $\Delta H^\circ_{298.15}$ value for the reaction was derived. The results obtained are presented as follows.

Reaction	Temperature, °K	Second Law Value	Third Law Value	Drift	$\Delta H^\circ_{298.15}$ kcal/mol
(1)	423	22.38	22.15	-	-132.0
(2)	473.15-723.15	23.06 ± 1.33	22.15	-1.67 ± 1.96	-131.2

Using the third law values for $\Delta H^\circ_{298.15}$, the corresponding $\Delta H^\circ_{298.15}$ (CuF₂, c) values were calculated. The adopted heat of formation for CuF₂(c) is $-131.2 \pm 0.8 \text{ kcal/mol}$.

Heat Capacity and Entropy.

The heat capacities, 298.15-1000°K, and $S^\circ_{298.15}$ were estimated by comparison with those for CuCl₂(c), CuF₂(c) and CaCl₂(c), respectively. The Cp values above 1000°K were obtained by graphical extrapolation.

Melting Data.

T_m was reported by H. M. Haendler, L. H. Towle, E. P. Bennett and W. L. Patterson, Jr., J. Am. Chem. Soc. 76, 2178 (1954). T_m for CuF₂(c) in HF(g) or H₂(g) was found to be $950 \pm 5^\circ\text{C}$ or $785 \pm 10^\circ\text{C}$, respectively, by H. von Wartenberg, Z. anorg. allgem. Chem. 241, 381 (1959). Heat of melting was estimated by comparison with those for other related compounds.

Heat of Sublimation.

See CuF₂(g) table for details.

OPW = 101.5368

(LIQUID)

COPPER DIFLUORIDE (CuF₂)

S_{298.15}^o = [20.584] gibbs/mol

ΔH_{298.15}^o = [-124.30] kcal/mol

ΔH_m^o = [9.4] kcal/mol

ΔH_v^o = [43.98] kcal/mol

T_m = 1043°K

T_b = [1722]°K

Heat of Formation.

The heat of formation (ΔH_{298.15}^o) was obtained from ΔH_{298.15}^o (CuF₂, c) by adding ΔH_m^o and the difference between H₁₀₄₃^o-H_{298.15}^o for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated based on an assumption that the average heat capacity for CuF₂(l) is 7.5 gibbs/atom. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See CuF₂(c) table for details.

Vaporization Data.

T_b is the temperature at which the free energy change for the reaction CuF₂(l) = CuF₂(g) becomes zero. The difference between ΔH_f^o for liquid and gas at T_b is ΔH_v^o.

Copper Difluoride (CuF₂)CuF₂

Heat of Formation.

The vapor pressures of CuF₂(c), at temperatures from 897 to 1026°K, have been determined by R. A. Kent, J. D. McDonald and J. L. Margrave, J. Phys. Chem. 70, 874 (1966). Based on these data, the heat of sublimation (ΔH_{sub}298.15) of CuF₂(c) was derived to be 62.45 ± 0.5 and 62.50 kcal/mol by the second and third law method, respectively. From the values of ΔH_{sub}298.15 and ΔH_f298.15 for CuF₂(c), the heat of formation (ΔH_f298.15) for CuF₂(g) was evaluated.

Heat Capacity and Entropy.

The molecular structure, bond distance and angle were estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The ground state electronic configuration, Σ_g⁺, was obtained from A. Böhler, J. L. Stauffer and W. Klemperer, Intern. Tech. Rept. No. 6, Apr. 30, 1964, Arthur D. Little, Inc., Cambridge, Mass. The other electronic levels and quantum weights were assumed from those for CuCl₂(g) reported by J. T. Hougen, G. E. Leroi and T. C. James, J. Chem. Phys. 33, 1670 (1961). The vibrational frequency, ν₂, was determined by P. H. Kasai, E. B. Whipple and W. Weltner, Jr., J. Chem. Phys. 44, 2581 (1966). The other two frequencies, ν₁ and ν₃, were calculated by Valence Force Treatment described by G. Herzberg, "Infrared and Raman Spectra," D. Van Nostrand Company, Inc., New York, 1945, using appropriate force constants. The principal moment of inertia is I = 1.66649 × 10⁻³⁸ g cm².

ΔHf° = Unknown

ΔHf°_{298.15} = -107.64 ± 2.0 kcal/molS°_{298.15} = [25.9] gibbs/molT₀ = 433°K

Heat of Formation.

The enthalpy change (ΔH°₄₃₃) for the reaction Cu(OH)₂(c) = CuO(c) + H₂O(g) has been determined by L. V. My, Bull. soc. chim. France, No. 3, 545 (1964). Based on the reported value, ΔH°₄₃₃ = 12 kcal/mol, the heat of formation (ΔHf°_{298.15}) for Cu(OH)₂(c) was derived as -107.64 kcal/mol, using ΔHf°_{298.15} = -37.250 and -57.798 kcal/mol for CuO(c) and H₂O(g), respectively, which was adopted here.

The free energy change (ΔG°_{298.15}) of the reaction Cu(OH)₂(c) = Cu⁺⁺(aq) + 2 OH⁻(aq) was evaluated to be 26.36 and 26.26 kcal/mol, based on the solubility product for Cu(OH)₂(c) reported by (1) E. S. Daniel, Zh. prikl. Khim. 37, 1358 (1964) and (2) N. P. Zhuk, Zh. Fiz. Khim. 28, 1523 (1954), respectively. Using values of S°_{298.15} and ΔHf°_{298.15} for Cu⁺⁺(aq) and OH⁻(aq) from "Selective Values of Chemical Thermodynamic Properties," Circular 500, National Bureau of Standards, 1952, and NBS Technical Note 270-1, 1955, by D. D. Wagman and co-workers, the corresponding enthalpy change ΔH°_{298.15} and heat of formation (ΔHf°_{298.15}) for Cu(OH)₂(c) were derived. The results obtained are presented as follows.

Chemical Reaction	ΔHf° _{298.15} kcal/mol	ΔHf° _{298.15} kcal/mol	Reference
Cu(OH) ₂ (c) = Cu ⁺⁺ (aq) + 2 OH ⁻ (aq)	10.06	-104.61	(1)
Cu(OH) ₂ (c) = Cu ⁺⁺ (aq) + 2 OH ⁻ (aq)	9.97	-104.52	(2)
CuO(c) + H ₂ O(l) = Cu(OH) ₂ (c)	-1.9	-107.5	(3)
CuO(c) + H ₂ O(l) = Cu(OH) ₂ (c)	0.3	-105.3	(4)

The heats of solution of CuO(c) and Cu(OH)₂(c) in HNO₃(aq.) have been determined by (3) de Forcrand, Compt. rend. 157, 441 (1913) to be -16.38 and -14.46 kcal/mol, respectively. From these data the enthalpy change for the reaction CuO(c) + H₂O(l) = Cu(OH)₂(c) was derived as -1.9 kcal/mol. For the same reaction, the enthalpy change was reported to be 0.3 kcal/mol by (4) P. Sabatier, Compt. rend. 125, 301 (1897). Based on ΔHf°_{298.15} = -37.25 and -68.315 kcal/mol for CuO(c) and H₂O(l), respectively, the heat of formation for Cu(OH)₂(c) was evaluated. The results obtained are presented in the above table.

Heat Capacity and Entropy.

The heat capacities, 298.15-700°K, were estimated by comparison with those for CuO(c), CaO(c) and Ca(OH)₂(c). The Cp values above 700°K were obtained by graphical extrapolation. S°_{298.15} was estimated such that the derived ΔGf° (Cu(OH)₂, c) = ΔGf° (CuO, c) + ΔGf° (H₂O, g) at 433°K.

Decomposition Temperature.

Td is the temperature at which the Gibbs energy change for the reaction Cu(OH)₂(c) = CuO(c) + H₂O(g) equals zero.

COPPER MONOXIDE (CuO)

(CRYSTAL)

OPW = 79.5394

CuO

$$\Delta H_f^\circ = -36.71 \text{ kcal/mol}$$

$$\Delta H_{298.15}^\circ = -37.25 \pm 0.5 \text{ kcal/mol}$$

$$S_{298.15}^\circ = 10.18 \pm 0.1 \text{ e.u.}$$

$$T_d = 1395^\circ\text{K}$$

Heat of Formation.

The more consistent data relative to the heat of formation are reviewed below. The selected value of -37.25 kcal/mol was derived from $\Delta H_{298}^\circ = -40.7$ kcal/mol for $\text{Cu}_2\text{O}(c)$ and $\Delta H_{298}^\circ = 33.80$ kcal/mol for $2\text{CuO}(c) = \text{Cu}_2\text{O}(c) + \text{O}_2(g)$. Four different sets of oxygen dissociation pressure measurements yield heats of reaction in close agreement with each other and with the aqueous calorimetry of Thomsen. Thomsen's data may be reduced to the heat of reduction of $\text{CuO}(c)$ with H_2 by combining heats of reaction for $\text{CuO} + \text{H}_2\text{SO}_4$, $\text{Fe} + \text{H}_2\text{SO}_4$, and $\text{Fe} + \text{CuSO}_4(aq)$. Direct calorimetric measurement of the heat of reduction by von Wartenberg and Werth yields $\Delta H_{298}^\circ = -36.04 \pm 0.2$ when corrected for incomplete condensation of water. Direct measurement is difficult and this value may correspond to incomplete reduction. The value of -35.02 reported by Wöhler and Jochum, *Z. physik. Chem.* **167A**, 169 (1933), is unreasonable. Equilibrium constants derived from Balesdent and Chiche yield -37.6 kcal/mol by third law analysis, but a serious entropy error is present. This is no doubt due to uncertainties in the activity of Cu in Cu-Au alloys. Other data have been reviewed by Randall, Nielsen and West, *Ind. Eng. Chem.* **23**, 388 (1931).

Heat Capacity and Entropy.

Low temperature values are based on data (15-297°K) from J. Fu and H. I. Johnston, *J. Am. Chem. Soc.* **75**, 2471 (1953). Earlier data from R. W. Miller (71-302°K), *J. Am. Chem. Soc.* **51**, 215 (1929), are in satisfactory agreement, while those of K. Clusius and P. Harteck (30-200°K), *Z. physik. Chem.* **134**, 243 (1929), are higher by several percent. A small anomaly in the heat capacity is observed in the region 210-230°K. Magnetic measurements of M. O'Keefe and F. S. Stone, *Phys. Chem. Solids* **23**, 261 (1952), and neutron diffraction studies of B. N. Brockhouse, *Phys. Rev.* **95**, 781 (1954), suggest that this is a Néel point associated with antiferromagnetism. The entropy was obtained from the heat capacities based on $S_{15}^\circ = 0.016$ e.u.

High temperature values are based on specific heats (373-1273°K) obtained from a dynamic method by D. M. Chishikov and A. S. Khirik, *Tr. Inst. Met. im. A. A. Baikova, Akad. Nauk SSSR*, No. 12, 79 (1963); cf. *Chem. Abn.* **59**, 5800 b (1963). Enthalpy data (523-1263°K) of Wöhler and Jochum, *loc. cit.*, lead to a value for S_{1200} lower by about 0.25 e.u., but this is inconsistent with the equilibrium data for $2\text{CuO} = \text{Cu}_2\text{O} + 0.5 \text{O}_2$.

Temperature of Decomposition.

T_d is calculated as the temperature at which ΔF equals zero for $2\text{CuO}(c) = \text{Cu}_2\text{O}(c) + 0.5 \text{O}_2(g)$.

Heat of Formation

The heat of formation is calculated from that of the crystal, $\Delta H_{298}^{\circ} = 36.1$ kcal/mol, which was obtained by 3rd law analysis of the sublimation pressure at 1273°K reported by Mack et al. (1). They employed a transpiration method and analysed for copper (in minute amounts) by its catalytic effect on the oxidation rate of sodium sulfite. The resulting pressure is only 100 times the predicted pressure of Cu(g) over CuO(c). Three pressures were reported but not used in the range 873-1173°K, since these yield a much smaller value for the heat of vaporization and imply a high dissociation energy.

Some estimates of D_0° CuO obtained by different methods are given below. These estimates along with a correlation of D_0° values for MnO, FeO, NiO and ZnO favor $D_0^{\circ} = 82 \pm 10$, close to the value adopted.

Method

Method	D_0°	ΔH_{298}°
Mack et al. (1) Transpiration	80.6	58.9
Arithmetic mean of D_0° for O ₂ and Cu ₂	82	57.7
Geometric mean of D_0° for O ₂ and Cu ₂	73	66.7
Linear Birge-Sponer extrapolation of A ² Π state	76.12	63.7212

Heat Capacity and Entropy

The visible spectrum of CuO has been extensively investigated, but only very recently has significant progress been made in its analysis. Antic-Jovanovic et al. (2) were able to obtain a vibrational analysis of the major band system by use of ⁶⁴Ni isotope studies. Shirk and Bass (3) recently reported absorption and fluorescence spectra in inert-gas matrices which allows assignment of the ground state and the first two excited states. They have strong evidence for the lower state of the blue system being the ground state and also for the second system, which corresponds to the red-orange system, originating in the upper state of the blue system. Thus, it is probable that the B state is ² Σ and the X and A states are both ² Π with very similar molecular constants, which serves to confuse the analysis of the spectra. It also appears likely that the 4187Å band analysed by Lagerqvist and Uhler (4) is a ² Π -² Π transition terminating in the ground state; thus we adopt their rotational constants for the X and C states. The vibrational frequencies and anharmonicities for the A and B states were from Antic-Jovanovic (2), as well as the vibrational interval for the ground state. The anharmonicity for the ground state was chosen so as to provide a reasonable Birge-Sponer extrapolation of the dissociation energy. The values of the ω_e were estimated from the Morse potential function relations. The rotational constants were assumed to be nearly constant. The values of the splitting in the electronic levels in the X and A states are from Antic-Jovanovic (2), and are roughly confirmed by Shirk and Bass (3).

The thermodynamic functions were calculated by summing over the individual partition functions for the separate states.

COPPER SULFATE (CuSO₄)

(CRYSTAL)

QFW = 159.6016

$$\Delta H_f^\circ = -181.66 \pm 0.2 \text{ kcal/mol}$$

$$\Delta H_f^{298.15} = -184.03 \pm 0.2 \text{ kcal/mol}$$

$$S_{298.15}^\circ = 26.11 \pm 0.1 \text{ gibbs/mol}$$

$$T_d = 1078^\circ\text{K}$$

Heat of Formation.

The heat of solution ($\Delta H_{298.15}^\circ$) of CuO(c) in sulfuric acid to form CuSO₄(c) has been measured by L. H. Adams and E. O. King, U. S. Bur. Mines RI 6617, 1965. From the reported value, $\Delta H_f^\circ = -5.61 \pm 0.09 \text{ kcal/mol}$ for the reaction CuO(c) + H₂SO₄(7.068 H₂O) = CuSO₄(c) + H₂O(l), the heat of formation ($\Delta H_f^{298.15}$) for CuSO₄(c) was evaluated as -184.03 kcal/mol, using $\Delta H_f^{298.15} = -37.25$, -209.49 and -68.315 kcal/mol for CuO(c), H₂SO₄(7.068 H₂O) and H₂O(l), respectively. See Fe₂(SO₄)₃(c) table for the sources of the last two $\Delta H_f^{298.15}$ values.

The equilibrium pressures for the following chemical reactions: (A) 2CuSO₄(c) = CuO·CuSO₄(c) + SO₃(g), (B) 3Cu(c) + CuSO₄(c) = 2Cu₂O(c) + SO₂(g), and (C) 4CuSO₄(c) + Cu₂O(c) = 3Cu₂O·CuSO₄(c) + SO₂(g), were determined by several investigators. For reaction (A), the partial pressures of SO₃(g) at different temperatures were calculated from the measured total pressures exerted by SO₃(g), SO₂(g) and O₂(g) produced by the reaction SO₃(g) = SO₂(g) + 1/2 O₂(g). From these vapor pressure data, the corresponding enthalpy changes ($\Delta H_{298.15}^\circ$) for the three reactions were evaluated by the second and third law methods. The results obtained are presented in the following table. The value of $\Delta H_f^{298.15}$ (CuSO₄, c) adopted was -184.03 ± 0.2 kcal/mol.

Investigator	Reaction	Temperature, °K	Second Law Value	Third Law Value	Drift	$\Delta H_f^{298.15}$ kcal/mol

(4) M. Randall, R. F. Nielsen and G. H. West, Ind. Eng. Chem. 23, 388 (1931). In this report, the high temperature equilibrium reactions of copper were critically reviewed.

Heat Capacity and Entropy.

The low temperature heat capacities, 52.67-296.29°K, were obtained from W. W. Weller, U. S. Bur. Mines RI 6659, 1965. The high temperature heat capacities were measured by H. Schottky, Z. phys. Chem. 54, 415 (1908), 282°K; R. Ewald, Ann. Physik., 44, 1213 (1914), 275-373°K; A. N. Krestovnikov and E. J. Peigins, J. Gen. Chem. USSR, 6, 1481 (1935), 288-873°K; and D. M. Chizhikov and A. S. Khirlik, Tr. Inst. Met. Im. A. A. Baikova, Akad. Nauk SSSR, No. 12 79-84 (1963), 373-1273°K. The heat capacities below 51°K were obtained from J. W. Stout, J. Chem. Phys. 9, 285 (1941). In that paper, the Cp values, 15-58°K, were plotted as function of temperature and the Cp curve shows a maximum at 34.8°K. In an attempt to evaluate the entropy due to the anomalous portion of the curve, a "normal" heat capacity curve was drawn. The entropy above the normal Cp curve is reported to be 0.48 eu, rather than a magnetic entropy of Rln2 = 1.377 eu. Apparently the magnetic entropy increases gradually above 40°K so that it is not feasible to separate the heat capacity due to magnetic effects from that of the crystal lattice.

The Cp values above 298.15°K were extrapolated smoothly by comparison with those for MnSO₄(c) (see FeSO₄(c) table for details). The adopted Cp values are close to the average of the reported Cp values.

The value of $S_{298.15}^\circ$ was derived using the low temperature Cp data reported by W. W. Weller, loc. cit., based on $S_{51}^\circ = 2.851 \text{ eu}$ evaluated from Cp data determined by J. W. Stout, loc. cit.

Decomposition Temperature.

T_d is the temperature at which the total pressure of the gaseous decomposition products equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for CuSO₄(c), determined by T. R. Ingraham, loc. cit.

Summarized below are the more consistent results for the heat of formation. The selected value of -40.7 kcal/mol is based on data from Thomsen and from Iwahara and Kimura. More recent equilibrium data yield essentially the same average for ΔHf but the separate values scatter by about ±0.7 kcal/mol and significant entropy errors are apparent.

Thomsen obtained values of -40.80, -40.87 and -41.51 from aqueous calorimetry using three different paths. He favored the first path which may be recalculated by combination of the heats of reaction of Cu₂O + H₂SO₄, Fe + H₂SO₄ and Fe + CuSO₄(aq) to yield the heat of reduction of Cu₂O with H₂. Direct measurements of the heat of reduction reported by L. Wöhler and N. Jochum, Z. physik. Chem. 157A, 169 (1933), appear to be unreliable since they lead to -43.0 for the heat of formation. The cell data of Iwahara and Kimura show very little drift and are in excellent agreement with Thomsen.

Heat Capacity and Entropy.

Low temperature values are based on data from L. V. Oregor (2.8-21°K), J. Phys. Chem. 56, 1845 (1952) and from J. Hu and H. L. Johnston (15-300°K), J. Am. Chem. Soc. 73, 4550 (1951). Earlier data by R. W. Miller (76-291°K), J. Am. Chem. Soc. 52, 215 (1929) are in satisfactory agreement. The entropy was obtained from the heat capacities based on S°₂₉₈ = 0.0015 eu.

High temperature values were obtained from specific heats (373-1273°K) determined with a dynamic method by D. M. Chisholm and A. S. Knirk, Tr. Inst. Met. in A. A. Baikova, Akad. Nauk SSSR, No. 12, 79 (1963); cf. Chem. Abs. 59, 79 (1963). Entropy data (545-1223°K) from Wöhler and Jochum, loc. cit., yield for S°₁₀₀₀ a value about 0.4 eu higher, but this is inconsistent with extensive equilibrium data for 2CuO(c) = Cu₂O(c) + 0.5 O₂ [see CuO(c)].

Melting Data.

For details see Cu₂O(l).

June 30, 1966

$$\Delta H^o_{298,15} = -32.029 \text{ kcal/mol}$$

$$\Delta H_m^o = 13.58 \pm 2 \text{ kcal/mol}$$

$$S^o_{298,15} = 22.901 \text{ gibbs/mol}$$

$$T_m = 1509^\circ\text{K}$$

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding ΔH_m^o and the difference between ($H^o_{1509} - H^o_{298}$) for the crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated on the basis of 8 gibbs per g atom, giving a value of 24 gibbs/mol which is essentially the same as that of the crystal at the melting point. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

T_m is the value recommended by S. J. Schneider, NBS Monograph 68, U. S. Govt. Printing Office, Washington, D.C., October, 1963, based on pressure-temperature-composition studies of H. S. Roberts and P. H. Smyth, J. Am. Chem. Soc. 43, 1061 (1921). The heat of melting was selected as 13.58 kcal/mol, corresponding to $\Delta H_m^o = 5 \text{ eu per g atom}$. A value of 13.4 kcal/mol has been derived from the Cu₂O-CuCl phase diagram by K. K. Kelley, USNM Bulletin 395, U. S. Govt. Printing Office, Washington, 1936. Another value may be obtained from oxygen dissociation pressures for the system Cu₂O(l)-CuO(c) determined by Roberts and Smyth, loc. cit. Equilibrium constants may be obtained for the reaction $2\text{CuO}(c) = \text{Cu}_2\text{O}(l) + 0.5 \text{ O}_2$ by assuming the activity of Cu₂O in the melt to be equal to its mole fraction. Based on the mole fractions given by Randall, Nielsen and West, Ind. Eng. Chem. 23, 388 (1931), the equilibrium data yield $\Delta H_m^o = 15.8 \pm 0.8 \text{ kcal/mol}$ by second law analysis of all points or 12.9 ± 1.6 by omission of 4 points at high pressure and low mole fraction. These results appear to be consistent with the selected value within the approximations involved.

Copper Oxide Sulfate ($\text{CuO} \cdot \text{CuSO}_4$)

(Crystal) $\Delta H_f^\circ = 233.141$

COPPER OXIDE SULFATE ($\text{CuO} \cdot \text{CuSO}_4$) (CRYSTAL)

$\Delta H_f^\circ = 233.141$

ΔH_f° = Unknown

$\Delta H_{298.15}^\circ = -221.7 \pm 0.3 \text{ kcal/mol}$

$S_{298.15}^\circ = [37.6 \pm 2] \text{ gibbs/mol}$

$T_d = 1136.4^\circ\text{K}$

Heat of Formation.

The equilibrium pressures for the following reactions: (A) $\text{CuO} \cdot \text{CuSO}_4(c) = 2\text{CuO}(c) + \text{SO}_2(g)$ and $\text{SO}_3(g) = \text{SO}_2(g) + 0.5 \text{ O}_2(g)$, and (B) $\text{CuO} \cdot \text{CuSO}_4(c) + \text{Cu}_2\text{O}(c) = 4\text{CuO}(c) + \text{SO}_2(g)$, were determined by (1) W. Reinhardt and P. Goudrian, Z. anorg. allgem. Chem. **156**, 85 (1923), and (2) T. R. Ingraham, Trans. Met. Soc. AIME, **233**, 359 (1968). Using the reported vapor pressures, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

Reference	Reaction	Temperature, °K	Second Law Value	Third Law Value	Drift, kcal/mol	$\Delta H_{298.15}^\circ$, kcal/mol
(1)	A	1013 - 1083	53.03 ± 2.53	52.43	-0.7 ± 2.4	-221.5
(2)	B	517 - 1027	41.72 ± 1.42	42.43	0.5 ± 1.4	-221.7
	A**	569 - 1136	50.92 ± 0.16	52.67	1.5 ± 0.2	-221.7

* Based on the third law value for $\Delta H_{298.15}^\circ$.

** Partial pressures were calculated from JANAF values for the $\text{SO}_3 - \text{SO}_2$ equilibrium. The value of $\Delta H_{298.15}^\circ$ ($\text{CuO} \cdot \text{CuSO}_4, c$) adopted is $-221.7 \pm 0.3 \text{ kcal/mol}$.

Heat Capacity and Entropy.

The heat capacities were calculated as the sum of those for $\text{CuO}(c)$ and $\text{CuSO}_4(c)$. The value of $S_{298.15}^\circ$ was estimated by comparison with those for $\text{CuO}(c)$ and $\text{CuSO}_4(c)$, and adjusted so that, using the derived free energy functions, the second and third law values for $\Delta H_{298.15}^\circ$ agree reasonably.

Decomposition Temperature.

T_d is the temperature at which the total pressure of the gaseous decomposition products of reaction (A) equals one atmosphere. It was obtained by graphical extrapolation of the decomposition pressures for $\text{CuO} \cdot \text{CuSO}_4(c)$, determined by T. R. Ingraham, loc. cit.

Dec. 31, 1960; June 30, 1961; Sept. 30, 1965

Heat of Formation.

The dissociation energy (D_0) of fluorine has been discussed by numerous investigators for many years. Until about fifteen years ago, high values of $D_0(F_2)$, about 65 kcal. mole⁻¹, were widely accepted. These values were obtained from extrapolations of the spectroscopic data for the halogens, e.g. $D_0 = 63.3$ kcal. mole⁻¹ was reported by H. V. Martenbergs, O. Sprenger and J. Taylor, Z. Physik. Chem., Bodenstein-Festband, 61 (1931). However, mean-while many indirect determinations as well as estimation have been carried out, which yield appreciably lower values. In 1950 the available data were examined critically by M. G. Evans, E. Warhurst and E. Whittle, J. Chem. Soc. 1952 (1950) and shown to support a value, $D_0(F_2) = 37 \pm 8$ kcal. mole⁻¹. The indirect determinations include (1) the thermal conductivity measurements by E. U. Franck and E. Wicke, Z. Elektrochem. 55, 643 (1951); (2) the explosion method by H. Fritz, Disert., Göttingen, 1952; (3) estimation by use of the relations between D_0 and the vibrational frequencies by A. Bucken and E. Wicke, Naturwiss., 37, 235 (1950); and (4) spectroscopic data on the dissociation energy of diatomic fluorides. Recently more direct methods have been used to determine $D_0(F_2)$. They gave similar values. The D_0 values reported by the previous investigators have been reviewed by L. Harter and C. W. Beckett, National Bureau of Standards Report 1435 (1952), and E. Wicke and H. Fritz, Z. Elektrochem. 57, 9 (1953).

The low bond dissociation energy of $F_2(g)$ has been attributed to the repulsion between the unshared electrons on the bound fluorine atoms by K. S. Pitzer, J. Am. Chem. Soc. 70, 2140 (1948), or to the absence in fluorine of strengthening of the bond by hybridization of the p- or d- orbitals as may take place in the higher halogens by R. S. Mulliken, J. Am. Chem. Soc. 77, 884 (1955). M. G. Brown, Trans. Faraday Soc. 55, 9 (1959) suggests that the observed low D_0 value results from the large energy required to promote the p atoms to the valence state from which the bond may be formed.

The equilibrium pressures for the reaction $F_2(g) \rightarrow 2F(g)$ have been measured by several investigators. Using the reported equilibrium constants, the dissociation energy, $D_{98.15}$, was evaluated by both the second and third law methods. The results obtained are presented as follows.

Temperature, °K.	2nd Law Value	3rd Law Value	Reference
759 - 1115	36.91 ± 0.41	37.76	1
810 - 950	36.7 ± 18.2	38.1	2
723 - 820	41.8 ± 0.2	36.0	4

1. R. N. Dorschner, J. Chem. Phys. 20, 330 (1952).

2. F. M. Ollies and J. L. Margrave, J. Chem. Phys. 21, 381 (1953).

3. H. Wise, J. Phys. Chem. 59, 389 (1954).

4. M. Farber, et al., "Study of Rocket Engine Exhaust Products", Thirteenth Quarterly Report, June 1 - Oct. 31, 1964, Westmont Corporation, Pasadena, California.

By use of H_2-F_2 mixture explosion method, $D_0(F_2)$ was reported as 37 ± 2 kcal. mole⁻¹ by E. Wicke and H. Fritz, loc. cit. K. L. Wray and D. F. Hornig, J. Chem. Phys. 23, 1271 (1956), using shock wave method, obtained $D_0 = 31.0 \pm 4.5$ kcal. mole⁻¹. The continuous absorption electronic spectrum of $F_2(g)$ and the Raman displacement for the $0 \rightarrow 1$ vibrational transition have been used by A. L. G. Rees, J. Chem. Phys. 26, 1567 (1957) to compute the potential energy curve for the repulsive Π_u state dissociating to two normal $F(g)$. This curve is consistent with the value, $D_0 = 37.1 \pm 0.85$ kcal. mole⁻¹. The absorption spectrum of $F_2(g)$ has been observed in the vacuum UV region by R. F. Izckowski and J. L. Margrave, J. Chem. Phys. 30, 403 (1959). From a progression of bands at 8744, the value, $D_0 = 37.5 \pm 2$ kcal. mole⁻¹ is deduced.

The F_2 dissociation energy is selected as 37.72 ± 0.80 kcal. mole⁻¹, yielding $\Delta H_f^\circ 298.15^\circ(P, g) = 18.86 \pm 0.40$ kcal. mole⁻¹.

Heat Capacity and Entropy.

The ground state configuration, electronic levels and quantum weights were taken from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949.

FLUORINE UNINEGATIVE ION (F⁻) (IDEAL GAS)

MOL. WT. = 18.99895

Ground State Configuration 1S₀
S_{298.15}° = 34.768 cal. deg.⁻¹ mole⁻¹
ΔH_f⁰ = -61.1 ± .5 kcal/mole
ΔH_f⁰ 298.15 = -62.2 ± .5 kcal/mole

Electronic Levels and Quantum Weight
C₁, cm.⁻¹ g₁
0.00 1

Heat of Formation.

The heat of formation was calculated from the equation: P(g) + e⁻ → F⁻(g) with the JANAP auxiliary value for P(g) using the measured electron affinity = 3.448 e.v. (79.511 kcal/mole) obtained from R. S. Berry and C. W. Reimann, J. Chem. Phys. 39, 1540 (1963). Other calculated values for the electron affinity are: 3.37 reported by E. Clementi and A. D. McLean, Phys. Rev. 135, A419 (1964); 3.08 e.v. E. Clementi, A. D. McLean, D. L. Raymond, and M. Yoshimine, 135, A1274 (1964); 3.50 e.v. B. Edlen, J. Chem. Phys. 33, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Neon. The electronic levels above 1 X 10⁵ cm.⁻¹ were omitted because their contribution is negligible below 6000°K. The h⁰-h₂₉₈ value at 0°K. is -1.481 kcal/mole.

Heat of Formation.

The dissociation energy (D₀) of FeF(g) was estimated as 4.64 ± 0.22 e.v. or 107 ± 5 kcal. mole⁻¹ by J. L. Margrave, "Optical Spectra and Molecular Parameters of Light Element Molecules", Progress Report No. 8, Jan. 1 to Mar. 31, 1965, William Marsh Rice University, Houston, Texas. From the value of D⁰ (Fe-F) the heat of formation (ΔH_f⁰ 298.15) for FeF(g) was derived to be 11.4 ± 5.0 kcal. mole⁻¹.

Heat Capacity and Entropy.

The ground state configuration and bond distance (r_e) were estimated by comparison with those for FeCl(g). The value of B_e was calculated using the relationship $B_e = \frac{2.7989 \times 10^{-39}}{I}$ where I = moment of inertia of FeF(g), and α_e was estimated by comparison with those for AlF(g), AlCl(g) and FeCl(g). The value of ω_e was derived from the bond distance, reduced mass and number of valence electrons according to the method given by K. M. Guggenheimer, Proc. Phys. Soc. (London) 59, 456 (1946), and the ω_ex_e was estimated from those for AlF(g), AlCl(g) and FeCl(g). The moment of inertia is 7.6259 × 10⁻³⁹ g. cm.²

HYDROGEN FLUORIDE (HF)

(IDEAL GAS)

GFW = 20.00637

Hydrogen Fluoride (HF)

(Ideal Gas) GFW = 20.00637

Ground State Configuration $1s^2$ $\Delta H_f^\circ = -65.13 \pm 0.2 \text{ kcal/mol}$ $S_{298.15} = 41.508 \text{ gibbs/mol}$ $\Delta H_f^\circ = -65.14 \pm 0.2 \text{ kcal/mol}$

Electronic Levels and Quantum Weights

$\epsilon_i, \text{cm}^{-1}$	g_i
0	1

$$\omega_e x_e = 4138.37 \text{ cm}^{-1} \quad \sigma = 1$$

$$\omega_e = 20.9557 \text{ cm}^{-1} \quad \alpha_e = 0.798^{-1} \quad r_e = 0.9168 \text{ \AA}$$

Heat of Formation

The selected value is obtained from a least squares, simultaneous solution (1) for the heats of formation of HF(g), HF(50 H₂O) and five closely related fluorides. Other results, based on 23 selected observations relating the 7 variables, are as follows in kcal/mol: HF(50 H₂O), -76.78 \pm 0.1; NaF(c), -137.52 \pm 0.2; BF₃(g), -271.42 \pm 0.4; CH₄(g), -223.04 \pm 0.3; NF₃(g), -31.43 \pm 0.3; and C₂F₄ (polymer), -198.2 \pm 0.7. The \pm values are approximate estimates of the overall uncertainty including systematic error. Further details of the simultaneous solution are given in (1).

The values given above require the use of certain auxiliary data; e.g., the value for NaF(c) presumes $\Delta H_f^\circ(\text{moln}) = 0.23 \pm 0.01$ and $\Delta H_f^\circ(\text{Na}^+(\infty \text{H}_2\text{O})) = -57.47 \pm 0.04 \text{ kcal/mol}$. Use of these auxiliary data leads to $\Delta H_f^\circ(298.15) = -79.82 \text{ kcal/mol}$ for HF($\infty \text{H}_2\text{O}$) and $F^-(\infty \text{H}_2\text{O})$; however, values for HF(n H₂O) should be obtained from that of HF(50 H₂O) by use of $[\phi_L(n) - \phi_L(50)]$ taken from the tables of Parker (2). This procedure should be reliable except in dilute solutions ($n > 1000$) where the equilibria $\text{HF} + \text{H}^+ + \text{F}^- + \text{HF} \rightleftharpoons \text{HF}_2^-$ yield an overall ΔH of about 3 kcal/mol. Parker (2) used thermodynamic data for these equilibria in order to calculate ϕ_L for the dilute solutions, but recent data (3-5) suggest that minor changes in the calculations may be desirable. For this reason the simultaneous solution includes $\phi_L(50) = 3184 \pm 300 \text{ cal/mol}$ (2) as an "observation" rather than as a fixed value. The result of the simultaneous solution is smaller by only 150 cal/mol, suggesting that $\phi_L(50)$ does not contain a major inconsistency.

Heat Capacity and Entropy

The ground state configuration is that deduced from UV spectra by Johns and Barrow (6). The excited state near 85000 cm^{-1} is omitted since its contribution to the thermodynamic functions is negligible. High-resolution studies of the vibration-rotation spectrum were reported by Mann et al. (7) and subsequently confirmed by others (8, 9). The analysis of Webb and Rao (9) is adopted for this table.

MOL. WT. = 36.00577

(IDEAL GAS)

HYPOFLUOROUS ACID (HF0)

Point Group C_{2v}
 $S^{\circ}_{298.15} = [53.954] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H^{\circ}_f 0 = [-30 \pm 10] \text{ kcal. mole}^{-1}$
 $\Delta H^{\circ}_f 298.15 = [-31 \pm 10] \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies

$\lambda, \text{ cm.}^{-1}$
 [1500] (1)
 [1065] (1)
 [3645] (1)

Bond Distances: H-O = [0.96] Å O-F = [1.41] Å
 Bond Angle: H-O-F = [104]°
 Product of the Moments of Inertia: $I_A I_B I_C = [1.2826 \times 10^{-117}] \text{ g.}^3 \text{ cm.}^6$
 $\sigma = 1$

Heat of Formation.

The value of $\Delta H^{\circ}_f 298.15$ for HF0(g) was calculated based on an estimated value for the heat of atomization 1.e. $\Delta H^{\circ}_f = 161.6 \text{ kcal. mole}^{-1}$ for the reaction $\text{HF0(g)} = \text{H(g)} + \text{F(g)} + \text{O(g)}$. The ΔH°_f value was assumed to be the sum of the F-O and H-O bond energies which were obtained from the corresponding bond energies in F₂O(g) and H₂O(g) molecules.

Heat Capacity and Entropy.

The H-O and F-O bond distances were assumed to be the same as those in the H₂O(g) and F₂O(g) molecules. The vibrational frequencies and H-O-F bond angle were estimated by comparison with the corresponding values for H₂O(g), F₂O(g) and Cl₂O(g). The three principal moments of inertia are $I_A = 0.1332 \times 10^{-39}$, $I_B = 3.0366 \times 10^{-39}$ and $I_C = 3.1699 \times 10^{-39} \text{ g. cm.}^2$

FH₃Si

Fluorosilane (H₃SiF) (Ideal Gas)

Mol. Wt. = 50.114
 $\Delta H_f^\circ 298.15 = [-105 \pm 15] \text{ kcal. mole}^{-1}$
 $S_{298.15}^\circ = 57.04 \pm 2 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 Point group C_{3v}
 Ground State Multiplicity = 1

Vibrational Frequencies and Degeneracies

ω_{cm}^{-1}	Deg.
2206 (1)	990 (1)
872 (1)	2196 (2)
943.4(2)	728.1(2)

Moments of Inertia: $I_A = 0.9784 \times 10^{-39} \text{ g. cm}^2$
 $I_B = 5.8578 \times 10^{-39} \text{ g. cm}^2$ $I_C = 5.8578 \times 10^{-39} \text{ g. cm}^2$
 $\sigma = 3$

Heat of Formation. $\Delta H_f^\circ 298.15$ was estimated in C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

Heat Capacity and Entropy. Vibrational levels and multiplicities were found in Henderson and Scheffee, op. cit. Moments of Inertia were calculated using the constants found in C. Newman, J. K. O'Loane, S. R. Polo, and M. K. Wilson, J. Chem. Phys. 25, 855 (1956).

$$r_e = 1.906 \text{ \AA}$$

$$\sigma^- = 1$$

Heat of Formation.

R. A. Durie and A. G. Gaydon, J. Phys. Chem. 56, 316 (1952), have obtained the dissociation limit (from the spectra) of IF as 23570 cm.⁻¹. The first excited states of F and I are 404 and 7599 cm.⁻¹ above the ground state respectively. There are two sets of dissociation products possible: $I(^2P_{1/2}) + F(^2P_{3/2})$ or $I(^2P_{3/2}) + F(^2P_{1/2})$. When corrected to the normal atoms, the observed limit gives $D_0(\text{IF}(g))$ 2.87 ± 0.04 e.v. or 66.18 ± 0.9 kcal. mole.⁻¹ and 1.96 ± 0.04 e.v. or 45.66 ± 0.9 kcal. mole.⁻¹ for dissociation energy respectively. Durie and Gaydon, loc. cit., favored the lower value. However L. Slutsky and S. H. Bauer, J. Am. Chem. Soc. 76, 270 (1954) have pointed out a numerical error in their calculations, which removes the chief support for the lower value and presented additional evidence favoring the higher value. More weight was given to the higher value which gives ΔH_f^o 59.15 = -22.648 ± 0.9 kcal. mole.⁻¹ for the reaction $1/2 I_2(c) + 1/2 F_2(g) = \text{IF}(g)$.

Heat Capacity and Entropy.

All molecular constants were obtained from W. H. Evans, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bur. of Standards 55, 147 (1955) except $r_e = 1.906$ \AA was obtained from L. G. Cole and G. W. Elverum Jr., J. Chem. Phys. 20, 1543 (1952) and ground state configuration was estimated by comparison with that for IFr and ICl from G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co., New York, 1950.

 $\Delta H_f^\circ = 16.905 \pm 0.05 \text{ gibbs/mol}$
 $T_m = 1131^\circ\text{K}$
 $\Delta H_f^\circ = -135.5 \pm 0.1 \text{ kcal/mol}$
 $\Delta H_f^\circ = -135.9 \pm 0.1 \text{ kcal/mol}$
 $\Delta H_m^\circ = 6.50 \text{ kcal/mol}$
 $\Delta H_m^\circ = 57.8 \text{ kcal/mol (to monomer)}$

Heat of Formation

The heat of solution of KF(c) in water has been measured by several investigators. Their results have been converted to ΔH_m° by Farker (5) and listed in the table below. Using $\Delta H_f^\circ = -4.24$, $\Delta H_f^\circ(\text{K}^+ \in \text{H}_2\text{O}) = -60.32$ (6), and $\Delta H_f^\circ(\text{F}^- \in \text{H}_2\text{O}) = -79.82 \text{ kcal/mol (7)}$, we obtain $\Delta H_f^\circ = -135.9 \pm 0.1 \text{ kcal/mol}$ which is adopted.

Investigator	Temperature, °K	Concentration, molality	No. of Determinations	ΔH_m° , kcal/mol
1. Guntz (1884)	291	0.28	1	-3.95
2. Forcrand (1911)	286	0.50	1	-4.54
3. Lange and Eichler (1927)	298	3.16 - 0.21	8	-4.24 ± 0.4
4. Lange and Martin (1937)	298	0.31	1	-4.01

Heat Capacity and Entropy

The low temperature heat capacities, 16-323°K, were measured by Westrum and Pitzer (8). The high temperature enthalpies, 298-530°K and 291-1187°K, were determined by Westrum and Pitzer (8), and Lyashenko (9), respectively. However, the high temperature Cp values derived from both sets appear to be inconsistent with the low temperature Cp values. The heat capacities derived from the enthalpy data of Westrum and Pitzer are too high (3% at 530°K and less at lower temperatures) to be joined smoothly with their low temperature Cp's. The adopted enthalpy at 530°K is about 1.4% lower than the reported value. The heat capacity derived from the enthalpy data of Lyashenko is 2.5% lower than the adopted one at 900°K. The differences are smaller at lower temperatures. At 900°K, the adopted enthalpy is 1.3% higher than the reported value. The adopted heat capacities in the temperature range, 323-2000°K, are estimated by graphical comparison with other alkali fluorides and chlorides, and joined smoothly with the low temperature data at 298°K.

S₂₉₈ is derived based on the adopted low temperature heat capacities.

Melting Data

See the KF(4) table.

Heat of Sublimation

The value of ΔH_{298}° is obtained as the difference between ΔH_f° for KF(c) and KF(g).

Potassium Fluoride (KF)

(Liquid)

GFW = 58.1004

POTASSIUM FLUORIDE (KF)

(LIQUID)

GFW = 58.1004

$$S_{298.15}^{\circ} = 16.167 \text{ gibbs/mol}$$

$$\Delta H_f^{\circ}{}_{298.15} = -132.519 \text{ kcal/mol}$$

$$T_m = 1131^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 6.50 \text{ kcal/mol}$$

$$T_b = 1790^{\circ}\text{K}$$

$$\Delta H_v^{\circ}(\text{to mixture}) = 33.9 \text{ kcal/mol of liquid}$$

Heat of Formation

The $\Delta H_f^{\circ}{}_{298}(t)$ is obtained from $\Delta H_f^{\circ}{}_{298}(c)$ by adding ΔH_m° and the difference between H_{1131}° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those of the alkali fluorides and chlorides, and is assumed to be constant in the temperature range, 298-3000°K. The Cp value, 16 gibbs/mol, derived from the enthalpy data of Lyashenko (12) appears low and is not adopted.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Tm has been reported as 1119 (1, 2), 1129 (3, 4), 1131 (5, 6), and 1153°K (7). The value 1131°K is adopted. Kelley (8) evaluated the following freezing-point data of binary systems: KF-AlF₃ (9), KF-K₂SO₄ (10), KF-KCl (11), KF-K₂CO₃ (13), and KF-K₂PO₄ (14), and derived the values of ΔH_m° (in kcal/mol) as 5.5, 5.55, 6.51, 7.1, and 7.1 respectively. The best value is recommended as 6.50 kcal/mol. Other reported ΔH_m° values are 6.70 (7) and 6.75 ± 0.1 kcal/mol (12). The value of heat of melting is tentatively adopted as 6.50 kcal/mol.

Vaporization Data

The boiling point (Tb) is calculated to be the temperature at which the partial pressures of KF(g) and K₂F₂(g) equal one atmosphere. The composition of the gaseous mixture in equilibrium with KF(l) at Tb is calculated as K₂F₂ 21.1% and KF 78.9%. The heat required to vaporize one mole of liquid at Tb is evaluated to be 33.9 kcal. The experimental values for the boiling point are 1778°K (1) and 1771°K (15).

Heat of Formation

The total vapor pressures of KF(g) and $K_2F_2(g)$ over KF(s, l) have been determined by many investigators using the boiling point (1, 2, 5), Knudsen-effusion (3), transpiration (4), and torsion-effusion (5) methods. A method of trial and error is employed to select the appropriate values for $\Delta H_{f298}^\circ(\text{KF}, \text{c})$ and $\Delta H_{f298}^\circ(\text{KF}, \text{g})$ such that by use of these two values and $\Delta H_{f298}^\circ = 50 \text{ kcal/mol}$ for the reaction $K_2F_2(g) = 2\text{KF}(g)$ and the Gibbs energy functions for KF(c), KF(l), KF(g), and $K_2F_2(g)$, the calculated total pressures of KF(g) and $K_2F_2(g)$ are consistent with the measured ones. Adopting $\Delta H_{f298}^\circ = 37.8$ and $\Delta H_{f298}^\circ = 54.42 \text{ kcal/mol}$, we evaluate the partial pressures of KF(g) and $K_2F_2(g)$ from the reported total pressure measurements. Based on the derived partial pressures for KF(g), the enthalpy changes for the processes: A. KF(c) = KF(g), and B. KF(l) = KF(g) are calculated by the second and third law methods. Using the third law ΔH_{f298}° and $\Delta H_{f298}^\circ = -135.90$ and $-132.519 \text{ kcal/mol}$ for KF(c) and KF(l), respectively, we obtain the ΔH_{f298}° for KF(g). The results are presented in the table below.

The dissociation energy (D_0) of KF(g) has been determined as $117 \pm 8 \text{ kcal/mol}$ by flame photometry by Page and Sugden (2), and Bulewicz, Phillips, and Sugden (5), yielding $\Delta H_{f298}^\circ(\text{KF}, \text{g}) = -77.6 \pm 8 \text{ kcal/mol}$. Barrow and Caunt (3) measured the fluctuation bands in the ultraviolet absorption spectra of KF and reported the upper limit for the $D_0(\text{KF}, \text{g})$ value to be 121.8 kcal/mol which leads to $\Delta H_{f298}^\circ(\text{KF}, \text{g}) = -81.4 \text{ kcal/mol}$ as the lower limit. Gaydon (10) reported $D_0 = 116.9 \pm 4.6 \text{ kcal/mol}$ for KF(g). The corresponding value of ΔH_{f298}° is calculated as $-77.5 \pm 4.6 \text{ kcal/mol}$.

The heat of formation for KF(g) at 298°K is adopted as $-78.1 \pm 0.5 \text{ kcal/mol}$.

Heat Capacity and Entropy

The rotational transition spectrum of KF(g) has been measured in the millimeter- and submillimeter-wave region with a high resolution molecular-beam absorption spectrometer by Veasey and Gordy (13). From the derived potential constants the vibrational constants were calculated. The reported values for ω_e , $\omega_e x_e$, B_e , α_e , and r_e are adopted.

Other values of ω_e reported are (in cm^{-1}): 390 ± 39 (11), 408 ± 28 (9), 429 ± 3 (12), and 426 ± 4 (13). The value of $\omega_e x_e$ has been determined as 1.45 cm^{-1} by Barrow and Caunt (3), and 2.4 cm^{-1} by Ritchie and Lew (12) and Baikov and Vasilevskii (13). Using the molecular beam electric resonance method, Green and Lew (14) measured the rotational transitions between the $J = 0$ and $J = 1$ states of K_2F_2 and reported the following values: $B_e = 0.27994 \text{ cm}^{-1}$, $\alpha_e = 0.002335 \text{ cm}^{-1}$, and $r_e = 2.17144 \pm 0.00005 \text{ \AA}$ which are in excellent agreement with the adopted values. By use of the same method, Grabner and Hughes (11) investigated the rotational Stark spectrum of K_2F_2 and reported the K-F bond distance for the zeroth vibrational state as $2.55 \pm 0.06 \text{ \AA}$.

Heat of Formation

The heats of solution and reaction of LiF(c) in water and hydrochloric acid have been measured by many investigators. The reported ΔH_{soln} values are listed in the table below. Using ΔH₂₉₈^o(Li⁺, ∞ H₂O) = -66.56 kcal/mol (8), and ΔH₂₉₈^o(F⁻, ∞ H₂O) = -79.82 kcal/mol (9), we calculate the corresponding ΔH₂₉₈^o values for LiF(c). Based on the heat of solution of LiOH(c) in excess HF solution measured by Sinko (7), the value, ΔH₂₉₈^o(LiF(c)) = -146.65 ± 0.5 kcal/mol is derived. The value of ΔH₂₉₈^o for LiF(c) is adopted as -147.45 ± 0.2 kcal/mol.

Investigator	Solvent	Temperature, °K	Concentration (LiF·nH ₂ O)	ΔH _r , kcal/mol	ΔH _f ^a , kcal/mol*	ΔH _f ^a , kcal/mol
1. de Forcrand (1911)	H ₂ O	289.2	unavailable	1.04	---	---

*The heat of dilution data of Parker (5) are used to convert ΔH_r to ΔH_f.

Heat Capacity and Entropy

Clusius, Goldman, and Perlick (10) measured the low temperature heat capacities in the temperature range 19 to 272°K and Clusius and Eichenauer (11) from 10 to 111°K. Below 20°K a number of investigators have reported values of θ_p, and the average value of 729 ± 6 is used here. The high temperature enthalpies from 298°K to the melting point 1121.3°K were measured by Douglas and Dever (12), and Voskresenskaya et al. (13). All these data are taken and smoothed by computer up to 400°K. Above 400°K the Cp values are obtained graphically by drawing a smooth line through the data points.

S₂₉₈ is derived from the adopted low temperature heat capacities, based on S₂₉₈^o = 0.064 eu.

Melting Data

See the LiF(4) table for details.

Heat of Sublimation

The difference between ΔH₂₉₈^o for LiF(g) and LiF(c) is ΔH_s^o₂₉₈.

Lithium Fluoride (LiF)

GFW = 25.9374

$$S_{298.15}^{\circ} = 10.269 \text{ gibbs/mol}$$

$$\Delta H_f^{\circ}{}_{298.15} = -143.081 \text{ kcal/mol}$$

$$T_m = 1121.3 \pm 1.0^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 6.474 \pm 0.005 \text{ kcal/mol}$$

$$T_b = 1990^{\circ}\text{K}$$

$$\Delta H_v^{\circ}(\text{to mixture}) = 35.08 \text{ kcal/mol}$$

Heat of Formation

The $\Delta H_f^{\circ}{}_{298}(l)$ is obtained from $\Delta H_f^{\circ}{}_{298}(c)$ by adding ΔH_m° and the difference between $H_{1121.3}^{\circ}$ and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

T. B. Douglas and J. L. Dever, J. Am. Chem. Soc. **76**, 4876 (1954), and N. K. Voskresenskaya, V. A. Sokolov, E. I. Banashek, and N. E. Schmidt, Akad. Nauk SSSR, Izvest. Sek. Fiz. - Khim. Anal. **27**, 233 (1956), have measured the enthalpies of LiF liquid to 1200 and 1400°K, respectively. Using the reported enthalpy data, a constant heat capacity is derived for each set. The adopted C_p for LiF(l) is the mean of the two derived heat capacities, and is extended arbitrarily to the temperatures above T_b and below T_m . The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point has been determined by many investigators. See the table below for details. The adopted value, 1121.3 \pm 1.0°K, is that reported by Douglas and Dever, loc. cit. The heat of melting is the mean of the ΔH_m° values reported by Douglas and Dever, loc. cit., and Voskresenskaya et al., loc. cit.

Vaporization Data

T_b is the temperature at which the partial pressures of LiF(g), $\text{Li}_2\text{F}_2(\text{g})$, and $\text{Li}_3\text{F}_3(\text{g})$, in equilibrium with LiF(l), equal one atmosphere. The vapor composition at the boiling point is evaluated as LiF 68%, Li_2F_2 26.6%, and Li_3F_3 4.4%. The heat required to vaporize one mole of liquid to form 0.739 mole of vapor mixture of the above composition at T_b is calculated to be 35.08 kcal.

The value of T_b for LiF(l) has been reported to be 1943 and 1949°K by O. Ruff, G. Schmidt, and S. Mugdan, Z. Anorg. Allgem. Chem. **223**, 83 (1922), and H. von Wartenberg and H. Schulz, loc. cit., respectively, which were obtained by extrapolation of their vapor pressure data, measured by the boiling point method.

Bond Distances: Li-O = [1.59] Å P-O = [1.41] Å

Bond Angle: P-O-Li = [104]°

$\sigma^- = 1$

Product of the Moments of Inertia: $I_{A,B,C} = [4.21884 \times 10^{-116}] \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The heat of formation ($\Delta H_f^\circ 298.15$) for LiFO(g) was calculated from $\Delta H_f^\circ 298.15 = 139 \text{ kcal. mole}^{-1}$ for the reaction $\text{LiFO(g)} = \text{Li(g)} + \text{F(g)} + \text{O(g)}$ where the value of $\Delta H_f^\circ 298.15$ was estimated to be the sum of the P-O and Li-O bond energies. The values of the P-O and Li-O bond energies were obtained from those in $\text{P}_2\text{O(g)}$ and $\text{Li}_2\text{O(g)}$ molecules, respectively.

Heat Capacity and Entropy.

The P-O and Li-O bond distances were assumed to be the same as those in $\text{P}_2\text{O(g)}$ and $\text{Li}_2\text{O(g)}$ molecules, respectively. The P-O-Li bond angle and vibrational frequencies were estimated by comparison with the corresponding values for the same oxide molecules. The three principal moments of inertia are: $I_A = 5.1543 \times 10^{-39}$, $I_B = 1.2729 \times 10^{-39}$ and $I_C = 6.4272 \times 10^{-39} \text{ g. cm.}^2$

Heat of Formation

The equilibrium constants for the decomposition of MgF(g) into Mg(g), MgF₂(c) and MgF₂(g) were determined by T. C. Ehler, Ph.D. Thesis, University of Wisconsin, 1963. Using this data, the heats of decomposition are evaluated by both the third and second law methods. The results are presented in the table below. The equilibrium constants for the reaction $\text{AlF}_3(\text{g}) + 2\text{Mg}(\text{g}) \rightarrow \text{AlF}(\text{g}) + 2\text{MgF}(\text{g})$ were also reported by T. C. Ehler, loc. cit. The heat of reaction is calculated by the third and second law methods, respectively. The dissociation energy (D_0°) of MgF(g) was reported to be 3.2 ± 0.7 and 4.2 eu by A. O. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953, and G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., 1950, respectively. The corresponding values of $\Delta H_{298.15}^\circ$ for MgF(g) are derived. The results are also listed in the table. The value of $\Delta H_{298.15}^\circ$ for MgF(g) adopted is the average of the first two $\Delta H_{298.15}^\circ$ values.

Investigator	Chemical Reaction	Third Law Value	Second Law Value	$\Delta H_{298.15}^\circ$ kcal/mol
T. C. Ehler	$2\text{MgF}(\text{g}) = \text{Mg}(\text{g}) + \text{MgF}_2(\text{g})$	-54.76 ± 0.74	-70 ± 19	$-52.8 \pm 1.3^*$
	$2\text{MgF}(\text{g}) = \text{Mg}(\text{g}) + \text{MgF}_2(\text{c})$	-126.66 ± 0.80	-92 ± 21	$-53.4 \pm 1.2^*$
G. Herzberg	$\text{AlF}_3(\text{g}) + 2\text{Mg}(\text{g}) = \text{AlF}(\text{g}) + 2\text{MgF}(\text{g})$	18.66 ± 0.40	2.7 ± 3.2	$-67.7 \pm 1.0^*$
A. O. Gaydon	$\text{MgF}(\text{g}) \rightarrow \text{Mg}(\text{g}) + \text{F}(\text{g})$	$D_0^\circ = 4.2 \text{ eV}$		-42.6 ± 16.1
	$\text{MgF}(\text{g}) \rightarrow \text{Mg}(\text{g}) + \text{F}(\text{g})$	$D_0^\circ = 3.2 \pm 0.7 \text{ eV}$		

*Based on $\Delta H_{298.15}^\circ$ value by the third law method.

Heat Capacity and Entropy

All the molecular constants are taken from G. Herzberg, loc. cit., except α_e which is estimated.

Dec. 31, 1960; June 30, 1965

NITROGEN MONOFLUORIDE (NF)

(IDEAL GAS)

MOL. WT. = 33.0051

Ground State Configuration [$\frac{1}{2}^-$]
 $S_{298.15}^\circ = 51.427$ cal. deg.⁻¹ mole⁻¹
 $\Delta H_f^\circ = 59.5 \pm 8$ kcal. mole⁻¹
 $\Delta H_f^\circ = 59.5 \pm 8$ kcal. mole⁻¹

Electronic Levels and Quantum Weight

$$\frac{\sum_i \epsilon_i \exp(-\epsilon_i/kT)}{0} \frac{g_1}{3}$$

$\nu_0 = 1115$ cm.⁻¹
 $B_0 = [-.923]$ cm.⁻¹
 $\nu_0 x_0 = [12.175]$
 $\Delta_0 = [-.0120]$
 $r_0 = [1.51 \text{ \AA}]$
 $\sigma = 1$

Heat of Formation.

The heat of formation was obtained by taking an average of two estimates of the dissociation energy of NF. The first estimate of 3.15 e.v. (72.4 kcal./mole) was obtained from W. C. Price, T. R. Pasmore and D. M. Roessler Discussions Faraday Soc. 55, 201 - 11 (1953). The second estimate of 70.4 kcal./mole was obtained by taking one-half the dissociation energy of NF₂ (g) calculated from JANAF values. The ΔH_f° 298.15 for NF (g) was then calculated with auxiliary JANAF data from a dissociation energy of 71.4 kcal./mole.

Heat Capacity and Entropy.

The M_e value was obtained from infrared studies of D. E. Milligan and M. E. Jacox, J. Chem. Phys. 40, 2461 (1964). The r_0 value was estimated from Guggenheimer's relation for single bonded molecules. [K. M. Guggenheimer, Proc. Phys. Soc. (London), 59, 456 (1946)] The anharmonicity constant x_0 was estimated by assuming the separation of the vibrational levels to be a linear function of the vibrational quantum number. The Δ_0 value was then calculated using the Morse potential function; B was determined from the bond length. The ground state configuration was assumed to be the same as that in NBr. The principal moment of inertia is 3.05247×10^{-39} g. cm.²

Heat of Formation

For the reaction 2NO(g) + F₂(g) → 2ONF(g), H. S. Johnston and H. J. Bertin, J. Am. Chem. Soc. 81, 8402 (1959), report ΔH_f° 298.15 = -74.8 ± 0.8 kcal., determined calorimetrically. This yields -15.7 ± 0.4 kcal. mole⁻¹ for ΔH_f° 298.15°.

Heat Capacity and Entropy

C. V. Stephenson and E. A. Jones, J. Chem. Phys. 20, 135 (1952), report the frequencies, obtained from the infrared spectrum, and moments of inertia, obtained from the microwave spectrum.

Heat of Formation.

The heat of reaction at 25°C for direct synthesis of nitryl fluoride from nitrogen dioxide with fluorine ($\text{NO}_2(\text{g}) + 1/2 \text{F}_2(\text{g}) = \text{NO}_2\text{F}(\text{g})$) has been measured calorimetrically as $-33.9 \text{ kcal. mole}^{-1}$ by J. D. Breasale and R. O. MacLaren, "Thermochemistry of Oxygen-Fluorine Bonding" (Final Tech. Summary Report, Contract No. Nonr 3433(00)), ARPA Order No. 184-62 United Technology Corporation, Sunnyvale, Calif., Mar. 1963. The heat of formation, $\Delta H_f^\circ = -28.0 \text{ kcal. mole}^{-1}$, for $\text{NO}_2\text{F}(\text{g})$ was then derived. The values of $\Delta H_f^\circ = -20 \pm 5$ and $-19 \pm 2 \text{ kcal. mole}^{-1}$ were issued in their second and third quarterly tech. reports, and have been quoted in the literature by E. Tschukow-Roux, J. Phys. Chem. 66, 1636 (1962).

G. Hetherington and P. L. Robinson, Special Publication No. 10, The Chem. Soc., London, 1957 quoted $\Delta H_f^\circ = 26 \text{ kcal. mole}^{-1}$ (presumably it has a minus sign) for $\text{NO}_2\text{F}(\text{g})$ which was derived from the heat of solution measured by Nichols and Robinson, a private communication to Hetherington and Robinson.

Heat Capacity and Entropy.

D. P. Smith and D. W. Magnuson, Phys. Rev. 87, 226 (1952), have measured the moments of inertia from microwave spectrum of $\text{NO}_2\text{F}(\text{g})$. In order to calculate the bond distances, given as N-F = 1.35 Å and N-O = 1.23 Å, the bond angle O-N-O was assumed to be 125°. The selected bond distances and angle were obtained from L. Clayton, Q. Williams and T. Wetherly, J. Chem. Phys. 30, 1328 (1959). Clayton et al. assumed the bond angle O-N-O in $\text{NO}_2\text{F}(\text{g})$ should be the same as that in $\text{NO}_2\text{Cl}(\text{g})$, and then calculated the bond distances N-F and N-O from Smith and Magnuson's data of the moments of inertia.

The selected vibrational frequencies were obtained from the infrared and Raman spectra measurements by R. Dodd, J. Rolfe and L. Woodward, Trans. Faraday Soc. 52, 145 (1956).

The three principal moments of inertia are $I_A = 6.3658 \times 10^{-39}$, $I_B = 7.3383 \times 10^{-39}$ and $I_C = 13.7041 \times 10^{-39} \text{ g. cm.}^2$

[800] (1)	[980] (1)
[680] (1)	[370] (1)
[1700] (1)	[130] (1)
[450] (1)	

Bond Distance: O-N = 1.29 ± 0.05 Å N-O' = 1.39 ± 0.05 Å O'-F = 1.42 ± 0.05 Å

Bond Angle: O-N-O = 125° ± 5° F-O'-N = 105° ± 5°

Angle between NO₂F plane and O₂NO' plane = 90°.

Product of the Moments of Inertia: I_AI_BI_C = 3.88637 X 10⁻¹¹⁴ g.³ cm.⁶

Heat of Formation.

The value, 2.5 ± 0.5 kcal. mole⁻¹, for the heat of formation of FNO₃(g) was obtained from R. Anderson, et al., "Thermochemistry of Oxygen-Fluorine Bonding," UTC 2002-Q74, United Technology Corporation, Sunnyvale, California, March 1, 1961, through February 28, 1962. The value of ΔH_f^o reported by O. G. Tsalkin, et al., Russ. J. Phys. Chem., 36, 561 (1962) was -4.2 ± 0.9 kcal. mole⁻¹ at 294°K.

Heat Capacity and Entropy.

Vibrational frequencies were estimated by comparison with those of HNO₃(g) reported by A. Palm and M. Kilpatrick, J. Chem. Phys. 23, 1562 (1955). Bond distances and angles were taken from L. Pauling and L. O. Brockway, J. Am. Chem. Soc. 59, 13 (1937). The three principal moments of inertia are 8.8598 X 10⁻³⁸, 1.8572 X 10⁻³⁸, and 2.3518 X 10⁻³⁸ g. cm.². The possible existence of restricted internal rotation in the molecule was not considered. Thus the values of C_p and S° calculated may be low.

(Crystal)

GFW = 41.9882

$$\Delta H_f^\circ = -136.95 \pm 0.2 \text{ kcal/mol}$$

$$\Delta H_f^\circ{}_{298.15} = -137.52 \pm 0.2 \text{ kcal/mol}$$

$$\Delta H_m^\circ = 7.97 \text{ kcal/mol}$$

$$\Delta H_f^\circ{}_{298.15} = 88.1 \text{ kcal/mol}$$

$$S^\circ_{298.15} = 12.24 \pm 0.02 \text{ gibbs/mol}$$

$$T_m = 1269 \pm 2^\circ\text{K}$$

Heat of Formation

The heats of solution and reaction of NaF(c) have been determined by many investigators. Incorporating their reported data with auxiliary $\Delta H_f^\circ{}_{298}$ values (1, 2), we calculate the corresponding values of $\Delta H_f^\circ{}_{298}$ (NaF, c). The results are presented in the table below. The adopted $\Delta H_f^\circ{}_{298}$ (NaF, c) is $-137.52 \pm 0.2 \text{ kcal/mol}$.

Investigator	Reaction*	Temperature, °K	Concentration NaF·nH ₂ O	No. of determinations	$\Delta H_f^\circ{}_{298}$ kcal/mol	$\Delta H_f^\circ{}_{298}$ kcal/mol
1. Guntz (1884)	A	285	400	1	0.13	-137.42
2. Latimer - Jolly (1953)	A	298	1850	2	0.23 ± 0.01	-137.52
3. Hepler et al. (1953)	A	298	1540	1	0.22 ± 0.01	-137.51
4. Davies - Benson (1965)	A	298	222	1	0.24 ± 0.01	-137.53
5. Thomsen (1882)	B	291	—	2	16.24 ± 0.15	-137.38
6. Wartenberg - Fitzner (1926)	C	293	—	1	-39.3 ± 0.1	-137.62
7. Schmitz - Schumaker (1947)	C	291	—	1	-39.5	-137.82
8. Coughlin (1958)	D	298	—	6	-1.40 ± 0.06	-137.58
9. Vorob'yev - Skuratov (1960)	E	298	—	5	-325.5 ± 2.2	-137.13

*A represents NaF(c) = NaF(n H₂O) and $\Delta H_f^\circ{}_{298} = \Delta H_f^\circ$; B, NaOH(200 H₂O) + HF(401 H₂O) = NaF(401 H₂O) + H₂O(l); C, NaCl(c) + 1/2 F₂(g) = NaF(c) + 1/2 Cl₂(g); D, NaCl(c) + HF(5.716 H₂O) = NaF(c) + HCl(12.731 H₂O); E, 4Na(c) + CF₄(g) = 4NaF(c) + C (graphite).

Heat Capacity and Entropy

The low temperature heat capacities, 0.05 - 15°K and 54.01 - 295.86°K, were measured by Harrison et al. (10) and King (11), respectively. These two sets of data are joined smoothly with the high temperature heat capacities at 298°K which were derived from the enthalpy measurements, 406.1 - 1282.2°K, determined by O'Brien and Kelley (12). The Cp values above 1282.2°K are obtained by linear extrapolation. S°_{298} is calculated using the adopted low temperature heat capacities and $S^\circ_{298} = 0.555 \text{ eu}$.

Frank (13) commented that the temperature measurements of O'Brien and Kelley (12) seemed to be about 20°K high at 1000°K with a smaller error at lower temperatures. A correction for the assumed error in the temperature measurement was used in the previous JANAF table. However, Douglas and Dittmars (14) have questioned this correction, since new enthalpy data for AlF₃ yielded Cp values in better agreement with the original Cp values of O'Brien and Kelley than with the corrected values of Frank. The $\alpha + \beta$ transition of AlF₃(c) was found in the range 723 - 6°K, while O'Brien and Kelley selected 727°K based on a point at 728.1°K in the β region and a point at 724.9°K in the pretransition region. Frank's correction yields an error of 9° at 727°K, yet the true error appears to be negligible (<2°) for AlF₃(c). Based on the above reasoning and the comparison of the Cp curve of NaF(c) with those of NaCl(c), LiCl(c), and LiF(c) in the temperature range 300 - 1300°K, we adopt the high temperature enthalpy data of O'Brien and Kelley without any correction.

The low temperature heat capacities in the temperature ranges 81 - 190 and 198 - 273°K were also measured by Koref (15); and high temperature enthalpies at temperatures 288 - 1073 and 290 - 1287°K were reported by Krestovnikov and Karetnikov (16), and Lyashenko (17), respectively. They are not used for evaluation.

Melting Data

See the NaF(l) table for details.

Heat of Sublimation

ΔH_{298}° is the difference between $\Delta H_f^\circ{}_{298}$ for NaF(g) and NaF(c).

Sodium Fluoride (NaF)

(Liquid)

GFw = 41.9882

SODIUM FLUORIDE (NaF)

(LIQUID)

GFw = 41.9882

 $S_{298.15}^{\circ} = 17.559$ gibbs/mol $\Delta H_f^{\circ} 298.15 = -130.545$ kcal/mol $T_m = 1269 \pm 2^{\circ}\text{K}$ $\Delta H_m^{\circ} = 7.97$ kcal/mol $\Delta H_f^{\circ}(\text{to mixture}) = 42.1$ kcal/mol of NaF(l) $T_b = 2060^{\circ}\text{K}$

Heat of Formation

 $\Delta H_f^{\circ}(\text{NaF}(l))$ is obtained from $\Delta H_f^{\circ}(\text{NaF}(c))$ by adding ΔH_m° and the difference between H_{1269}° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

The heat capacities of NaF(l) are derived from the enthalpy data, 1287.6 - 1746.5°K, determined by O'Brien and Kelley (1). A glass transition temperature is assumed at 900°K, i.e. the heat capacities below 900°K are taken from those for NaF(c). The Cp values above 1746.5°K are obtained by extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data

The value of T_m has been reported as (°K): 1313 (2), 1285 (3), 1270 (3, 4, 5), 1269 (6), 1268 (7, 8, 9), 1267 (10, 11, 12), 1265 (13), 1263 (14), and 1253 (15). We select $T_m = 1269^{\circ}\text{K}$. The value 1285°K reported by O'Brien and Kelley seems unreasonably high and is not adopted. The cause of this discrepancy is still unresolved (17). The heat of melting is calculated as the difference between the adopted enthalpies for NaF(c) and NaF(l) at 1269°K. Kelley (18) derived $\Delta H_m^{\circ} 1265$ to be 5.82 - 8.43 kcal/mol, based on 13 sets of molten salts equilibrium data involving NaF. The value $\Delta H_m^{\circ} 1285 = 8.03$ kcal/mol reported by O'Brien and Kelley is not used.

Vaporization Data

T_b is the temperature at which the partial pressures of NaF(g) and Na_2F_2 (g) in equilibrium with NaF(l) equal one atmosphere. The vapor composition at T_b is evaluated as NaF 84.84 and Na_2F_2 15.24. The heat required to vaporize one mole of liquid to form 0.868 mole of vapor mixture of the above composition at T_b is calculated to be 42.1 kcal/mol. Ruff et al. (16) measured the vapor pressure of NaF(l) in the temperature range of 1699 - 1974°K and reported $T_b = 1978^{\circ}\text{K}$.

Ground State Configuration $1s^2$ $\Delta H_f^\circ = -69.03 \pm 0.5 \text{ kcal/mol}$ $\Delta H_f^\circ = -69.03 \pm 0.5 \text{ kcal/mol}$ $\Delta H_f^\circ = -69.03 \pm 0.5 \text{ kcal/mol}$ $\Delta H_f^\circ = -69.03 \pm 0.5 \text{ kcal/mol}$

Electronic Levels and Quantum Weights

 $\frac{g_i}{g_0} = 1$ $\omega_e = 536.10 \pm 0.35 \text{ cm}^{-1}$ $\sigma = 1$ $\omega_e x_e = 3.83 \pm 0.14 \text{ cm}^{-1}$ $r_e = 1.9260 \text{ \AA}$

Heat of Formation

The total pressures of NaF(g) and Na₂F₂(g), in equilibrium with NaF(c, s) at temperatures 1020 - 1974°K, have been determined by many investigators, using manometric (1, 2, 3), torsion-effusion (6, 8), Knudsen-effusion (3, 7), transpiration (4), and molecular-beam velocity-selector (9, 10) methods. In order to evaluate ΔH_f° (NaF, g) we have used a trial and error variation of ΔH_f° and ΔH_v° for the monomer and dimer such that the ΔH_f° values derived by the second and third law methods are in reasonable agreement.

Incorporating ΔH_f° = 68.1 and ΔH_v° = 61.12 and 58.75 kcal/mol for NaF and Na₂F₂, respectively, with JANAF functions for NaF(c), NaF(s), NaF(g) and Na₂F₂(g), we derive the partial pressures of NaF monomer from the reported total pressures. Based on the calculated partial pressures of NaF(g), the corresponding heats of vaporization are evaluated by the second and third law methods. Using the third law ΔH_f° and ΔH_v° = -137.52 and -130.545 kcal/mol for NaF(c) and NaF(s), we obtain values of ΔH_f° for NaF(g). The results are presented in the table below. The ΔH_f° (NaF, g) value adopted is -69.42 kcal/mol.

The vapor pressure data reported by Miller and Kusch (3) and Eisenstadt et al. (10) are not consistent with the other sets and are not used for evaluation.

Gaydon (11) and Herzberg (12) reported $D_0^\circ = 114.2 \pm 6.9$ (4.95 \pm 0.3 eV) and ≤ 122.2 kcal/mol (5.3 eV), respectively. Using JANAF ΔH_f° values for NaF(c) and F(g), we obtain ΔH_f° (NaF, g) = -70.5 \pm 5.8 and -78.5 kcal/mol. Employing flame-photometric method, Bulevskii et al. (13) and Page and Sugden (14) derived $D_0^\circ = 121 \pm 7$ and 119 ± 120 kcal/mol for NaF(g), which lead to ΔH_f° (NaF, g) = -77.3 \pm 7 and -75 to -76 kcal/mol.

* Data points calculated from a given total pressure equation.

** Process A: NaF(c) = NaF(g); B: NaF(s) = NaF(g).

Heat Capacity and Entropy

Veazey and Gordy (15) have measured the rotational transitions of NaF in the millimeter- and sub-millimeter-wave region with a high-resolution molecular-beam absorption spectrometer. The derived values of ω_e , $\omega_e x_e$, B_e , $B_e x_e$ and r_e are adopted here.

Using the molecular beam electric resonance method, Bauer and Lew (16) measured the transition between the $J = 0$ and $J = 1$ rotational levels of Na₂F₂ in the three lowest vibrational states. Radio-frequency transitions for Na₂F₂ have been observed by Hollowell et al. (19). Infrared spectra of NaF have been analyzed by Snellson and Pitzer (17), Ritchie and Lew (18), and Baikov and Vasilevskii (20). The molecular constants derived by the above authors are similar to the values adopted, except the value $\omega_e = 550 \text{ cm}^{-1}$ (17) which is different from the value 536.1 cm^{-1} reported by Veazey and Gordy (15).

FLUORINE MONOXIDE (FO)

(IDEAL GAS)

GFW = 34.998

Ground State Configuration [2Π]

S_{298.15} = 51.77 ± 0.3 gibbs/molΔH_f⁰ = [26 ± 10] kcal/molΔH_f⁰_{298.15} = [26 ± 10] kcal/mol

Electronic Levels and Quantum Weights

ϵ_i , cm ⁻¹	$\frac{g_i}{[29000]}$	$\frac{g_i}{[4]}$
0	[4]	[4]
1056 cm ⁻¹		
$w_e = 1056$ cm ⁻¹		
$B_e = [1.148]$ cm ⁻¹		
$w_{exe} = [15]$ cm ⁻¹		
$\alpha_e = [0.020]$ cm ⁻¹		
$r_e = [1.30]$ Å		
$\sigma = 1$		

Heat of Formation

Several values have been proposed for the heat of formation of FO(g). V. H. Dibeler, R. M. Reese and J. L. Franklin, J. Chem. Phys. 27, 1296 (1957), obtained D₀(FO,g) = 24 kcal from electron impact studies. However, theoretical estimates give D₀ values in the range 45 - 56 kcal. W. C. Price, T. R. Passmore and D. M. Roessler, Discussions Faraday Soc. 25, 207 (1963), estimated 52 kcal for D₀(FO,g).

From a consideration of the central bond energies in FNOH and HNOH with that in HOOH, using all JANAP values of 101, 109 and 50 kcal, we predict the bond dissociation energy in FO-OF to be 46 ± 4 kcal, which yields D₀(FO,g) = 51 ± 2 kcal. The average F-O bond dissociation energy in F₂O(g) is 49.8 ± 0.5 kcal. Also, since there is one less antibonding electron in FO than in F₂, we should expect the F-O bond to be greater than that in F₂(38 kcal). Thus a median value of D₀(FO,g) = 51.4 ± 10 kcal is adopted here which leads to ΔH_f⁰(FO) = 26 kcal/mol.

Heat Capacity and Entropy

The fundamental frequency is obtained by adding 2 $\omega_e x_e$ to the value reported by A. Arkell, R. R. Reinhard and L. P. Larson, J. Am. Chem. Soc. 87, 1016 (1965), from matrix isolation studies. The bond length was taken equal to that in the isoelectronic molecule O₂(g). The value of $\omega_e x_e$ was obtained from the Morse potential function and the assumed dissociation energy. The rotational constant α_e was also estimated from the above parameters and the Morse potential curve. The 2Π ground state is that predicted by molecular orbital theory and the first excited state would also be 2Π. By analogy with the isoelectronic O₂⁻(g) states, the first excited level was estimated at 29000 cm⁻¹.

Bond Distances: Ti-O = [1.62] Å Ti-F = [1.74] Å

Bond Angle: O-Ti-F = [180°]

Rotational Constant: B₀ = [0.1705] cm.⁻¹

Heat of Formation.

ΔH°_f 0 was estimated as -103 kcal. mole⁻¹ by J. S. Gordon, AstroSystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. ΔH°_f 298.15 was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. Principal moment was 16.419 X 10⁻³⁹ g. cm.²

F₀₂

OPW = 50.9972

(IDEAL GAS)

MONOFLUORINE DIOXIDE (F₀₂)

Point Group C_{2v}
S_{298.15} = 51.9 gibbs/mol
Ground State Quantum Weight = 2
ΔH_f^o = 3.4 ± 5 kcal/mol
ΔH_f^o_{298.15} = 3.0 ± 5 kcal/mol

Vibrational Frequencies and Degeneracies

ω, cm ⁻¹	
1495.0 (1)	
584.5 (1)	
376.0 (1)	

Bond Distance: O-O = 1.22 Å O-P = 1.58 Å

Bond Angle: O-O-P = 109.5°

Product of the Moments of Inertia: I_AI_BI_C = 7.7504 × 10⁻¹¹⁶ g³cm⁶

G° = 1

Heat of Formation.

The heat of formation for F₂O₂(g) is unavailable in the literature. Based on a kinetic study of the thermal decomposition of F₂O₂(g) reported by H. J. Schumacher and P. Frieck, Z. physik. Chem. **B24**, 332 (1934), the enthalpy change for the reaction F₂O₂(g) = F(g) + O₂(g) was estimated to be + 17.3 kcal/mol by J. B. Levy and B. K. Healey, J. Phys. Chem. **69**, 408 (1965), assuming that the activation energy for the reverse reaction is negligible. From this data the value of ΔH_f^o_{298.15}(F₂O₂, g) was calculated as + 3.2 kcal/mol, using ΔH_f^o_{298.15} = + 4.73 kcal/mol for F₂O₂(g) determined calorimetrically by A. D. Kirshenbaum, A. V. Grosse and J. G. Aston, J. Am. Chem. Soc. **81**, 6398 (1959).

Based on the assumption that the enthalpy change for the reaction F₂O₂(g) = F(g) + O₂(g) is 16.5 kcal/mol, which is half of the enthalpy change for the reaction F₂O₂(g) = 2F(g) + O₂(g), the heat of formation (ΔH_f^o_{298.15}) for F₂O₂(g) was derived as + 2.4 kcal/mol.

The value of ΔH_f^o_{298.15}(F₂O₂, g) adopted is 3 ± 5 kcal/mol.

Heat Capacity and Entropy.

The vibrational frequencies for F₂O₂(g) were assumed to be the same as those obtained from matrix isolation by P. N. Noble and G. C. Pimentel, J. Chem. Phys. **44**, 3641 (1966). These authors have observed two more frequencies for isotopically substituted F₂O₂ and combined them with those observed by R. D. Spratley, J. J. Turner and G. C. Pimentel, J. Chem. Phys. **44**, 2063 (1966), and performed a normal coordinate analysis. The results confirm the fact that the bond distances and angles in F₂O₂ are essentially the same as those reported for F₂O₂(g) by R. H. Jackson, J. Chem. Soc., 4585 (1962). The same molecular structure for F₂O₂ was also deduced from electron spin resonance and electron paramagnetic resonance data reported by R. W. Fessenden and R. H. Schuler, J. Chem. Phys. **44**, 434 (1966) and P. H. Kasal and A. D. Kirshenbaum, J. Am. Chem. Soc. **87**, 3069 (1965), respectively. Hence this molecular structure was adopted. Two vibrational frequencies, ν₁ and ν₃, for F₂O₂ molecule were also observed by A. Arkell, J. Am. Chem. Soc. **87**, 4057 (1965).

The three principal moments of inertia are: I_A = 1.1103 × 10⁻³⁹, I_B = 7.8182 × 10⁻³⁹ and I_C = 8.9285 × 10⁻³⁹ g cm².

Dec. 31, 1960; Sept. 30, 1962

Phosphorus Monofluoride (PF) (Ideal Gas)

Mol. Wt. = 49.975

 $\Delta H_f^\circ 298.15 = -14 \pm 3 \text{ kcal. mole}^{-1}$ $S^\circ 298.15 = 53.7 \text{ cal. deg}^{-1} \text{ mole}^{-1}$ Ground State Configuration \sum

Electronic Level and Multiplicity

 $\epsilon, \text{ cm}^{-1}$ g_1 0 3 $\omega_e X_e = 4.409 \text{ cm}^{-1}$ $B_e = 0.5665 \text{ cm}^{-1}$ $\alpha_e = 0.00456 \text{ cm}^{-1}$ $r_e = 1.590 \text{ \AA}$ $\sigma = 1$

Heat of Formation, $\Delta H_f^\circ 298.15$ was derived from a D_0° calculated with spectroscopic constants reported by A. E. Douglas and M. Preckowiak, Can. J. Phys. 40, 832 (1962). The D_0° value was calculated using the dissociation and spectroscopic relations given by G. Herzberg in "Spectra of Diatomic Molecules", D. van Nostrand Co., N. Y., 2nd Ed. (1950) pages 93 and 100. If the PF molecule dissociates to the ground state atoms, $F(3s/2) + F(2p_{3/2})$, the corresponding $\Delta H_f^\circ 298.15$ is $-15 \pm 3 \text{ kcal. mole}^{-1}$. If the dissociation is to the phosphorus ground state and the excited fluorine state, $F(3s/2) + F(2p_{1/2})$, the corresponding $\Delta H_f^\circ 298.15$ is $-14 \pm 3 \text{ kcal. mole}^{-1}$. The dissociation to an excited $F(2p_{1/2})$ atom was assumed to obtain the selected $\Delta H_f^\circ 298.15 = -14 \pm 3 \text{ kcal. mole}^{-1}$.

The heat of formation was estimated to be $-17 \text{ kcal. mole}^{-1}$ by J. S. Gordon, "Thermodynamic Data for Combustion Products", January, 1960, Thiokol Chemical Corp. This estimate when changed from white(Ox) to red(V) phosphorus reference state ($-13 \text{ kcal. mole}^{-1}$) agrees within uncertainty limits with the derived $\Delta H_f^\circ 298.15$ values.

Heat Capacity and Entropy. The molecular constants were reported by Douglas and Preckowiak (loc. cit.). They photographed and analyzed the electronic spectra of PF in the emission spectrum of a discharge through a mixture of PF_3 and He.

PHOSPHORUS SULFIDE FLUORIDE (PSF)

(Ideal Gas)

Mol. Wt. = 82.041

ΔH°_f 298.15 = [-37 ± 15] kcal. mole⁻¹

S°_{298.15} = [86.35 ± 3] cal. deg.⁻¹ mole⁻¹

Ground State Multiplicity = 1

Vibrational Frequencies and Degeneracies

ω cm. ⁻¹	[940] (1)	[740] (1)	[400] (1)
940	1	1	1
740	1	1	1
400	1	1	1

Product of the Moments of Inertia: I_AI_BI_C = [7.999 X 10⁻¹¹] g.³ cm.⁶ σ = 1

Heat of Formation. The ΔH°_f 298.15 was estimated by C. B. Henderson and R. S. Scheffee, Atlantic Research Corp., Alexandria, Virginia, "Survey of Thermochemical Data," January, 1960. This estimated ΔH°_f 298.15 was corrected for the change in the reference state of phosphorus from white α to red γ.

Heat Capacity and Entropy. The vibrational frequencies were estimated by comparison with the corresponding frequencies of PF₃(g), PS(g), and PF₂(g). The vibrational levels of PF₂(g) in turn were estimated by J. S. Gordon, Thokol Corp., Reaction Motors Division, Denville, N. J., "Thermodynamic Data for Combustion Products," January, 1960. The entropy was estimated by C. B. Henderson and R. S. Scheffee (loc. cit.). The product of the moment of inertia was derived from the estimated entropy.

Heat of Formation

Ehlert and Margrave (1) have studied mass-spectrometrically the reaction $Si(g) + SiF_2(g) \rightarrow 2SiF(g)$ by monitoring the intensities of the Si^+ , SiF_2^+ , and SiF^+ ions in an equilibrium system containing CaF_2 and Si. The ionization cross-sections are assumed to cancel so that equilibrium constants can be obtained directly from the ion intensities. We have analysed the above data using present JANAF functions and obtain $\Delta H_{298}^\circ = 23.5 \pm 3$ kcal by the third law technique with a drift of -0.8 ± 1.1 eu, the second law value is 23.9 ± 7 kcal. We adopt the third law value which with JANAF auxiliary data gives $\Delta H_f^\circ(SiF, g) = -4.6 \pm 3$ kcal/mol.

Johns and Barrow (2) have selected $\Delta H_f^\circ(SiF, g) = 115 \pm 10$ kcal/mol, from Birge-Sponer extrapolations of several states, this gives $\Delta H_f^\circ = 0.1 \pm 10$ kcal/mol in good agreement with the adopted value.

Heat Capacity and Entropy

The molecular constants of the various electronic levels have been documented by Johns and Barrow (2), Verma (3), Barrow et al. (4), and Appelblad et al. (5). The approximation involving the use of the ground state constants for all electronic levels is used since it introduces negligible error in this molecule.

Heat of Formation

The heat of formation, ΔH_{298}° , of TiF(g) is calculated from the dissociation energy, D_0° . The dissociation energy is estimated as 148 ± 6 kcal/mol using the corresponding quantity for TiF₂(g) and the relation $D(\text{HF})/D(\text{HF}_2) = 0.46 \pm 0.02$ which Zmbov and Margrave (1) found held for other mono- and di-fluorides.

Heat Capacity and Entropy

The vibrational frequency, ω_e , and anharmonic vibrational term, $\omega_e x_e$, are estimated from those of the alkali and mercury monohalides. The interatomic distance, r_e , is estimated from those of TiCl(g), TiF₂(g) and TiF₃(g). B_e is calculated from r_e . The ground state term and electronic levels are estimated from the ground state multiplet of Ti²⁺ (2).

 $B_e = [0.2923] \text{ cm}^{-1}$

Heat of Formation

The heat of formation, ΔH_f^o₂₉₈(WF, g) = 92.3 kcal/mol, is calculated from the bond dissociation energy D₂₉₈^o(WF) = 130 ± 15 kcal/mol. This value of D₂₉₈^o is estimated to be slightly higher than the average bond dissociation energy of WF₆(g) by analogy with the MO_x system.

Heat Capacity and Entropy

The bond distance is estimated to be the same as that in WF₆(g). This distance is then used with Ouggenheimer's relation to calculate the fundamental vibrational frequency, w_e (K. M. Ouggenheimer, Proc. Phys. Soc. 58, 456 (1946)). The anharmonicity correction x_e is estimated roughly by assuming $x_e = w_e/(D_0 + 0.5 w_e) = 0.0042$. The rotational constant B_e is calculated from the estimated bond distance. The value of w_e is calculated from the Morse potential function. The moment of inertia is $9.575 \times 10^{-39} \text{ g cm}^2$.

The ground state configuration, low lying electronic levels and their quantum weights are estimated based on the tentative molecular orbital diagram for TaO given by M. Weltner, Jr., and D. McLeod, Jr., J. Chem. Phys. 42, 882 (1965). Using this scheme, we obtain the ground state configuration as $\pi^2 \sigma^2$, which yields a $^2\Delta$ ground state. The first excited state is assumed to have $\pi^2 \sigma^2$, which yields a $^2\Delta$ state. Higher levels are considered to be formed by transition to π^* antibonding orbitals, and by analogy with TaO these are assumed to lie in the 15000 cm⁻¹ region. The degeneracy of these levels is estimated roughly from the large number of possible configurations.

$$\Delta H_f^\circ = (20.0 \pm 5) \text{ kcal/mol}$$

$$\Delta H_{298.15}^\circ = (19.8 \pm 5) \text{ kcal/mol}$$

$$\Delta H_f^\circ = (20.0 \pm 5) \text{ kcal/mol}$$

$$\Delta H_{298.15}^\circ = (19.8 \pm 5) \text{ kcal/mol}$$

$$\omega_e = (628.0) \text{ cm}^{-1} \quad \sigma = 1 \quad \omega_e x_e = [4.0] \text{ cm}^{-1}$$

$$B_e = [0.29899] \text{ cm}^{-1} \quad r_e = [1.90] \text{ \AA}$$

Heat of Formation

Based on $[D(ZrF_2)/D(ZrF_2)] = 0.46$, as indicated by recent work on the fluorides of Groups II and IV elements (1, 2, 3, 4, 5), and $D_0(ZrF_2) = 318.1 \text{ kcal/mol}$, the $D_0(ZrF)$ is calculated as 146.3 kcal/mol . Using $\Delta H_f^\circ(Zr, g) = 147.99$, $\Delta H_f^\circ(F, g) = 18.36$, and $D_0(ZrF, g) = 146.3 \text{ kcal/mol}$, we derive $\Delta H_f^\circ(ZrF, g) = 20.0$ or $\Delta H_f^\circ(ZrF, g) = 19.8 \pm 5 \text{ kcal/mol}$ which is adopted. The ΔH_{298}° for $ZrF(g)$ was evaluated as approximately $16 \pm 5 \text{ kcal/mol}$ by Nard and Hildenbrand (8), employing different $D(ZrF_2)$ values. Their value is in agreement with the adopted one, within the assigned uncertainty.

Heat Capacity and Entropy

The ground state configuration is taken from the ground state multiplet of Zr^+ (6). The electronic levels are estimated as three times higher than those of $TiF(g)$ and the quantum weights are assumed to be the same. ω_e is taken to be approximately the same as the $Zr-F$ stretching frequency ν_1 for $ZrF_4(g)$. B_e is calculated from the formula $B_e = (2.798076 \times 10^{-39})(I_e)^{-1}$ where $I_e = \mu r_e^2$, μ = reduced mass of $ZrF(g)$, $r_e = 1.90 \text{ \AA}$ which is estimated from those of ZrF_2 , CF_4 , CF and other related gaseous molecules. σ_0 is derived from B_e , ω_e , and $\omega_e x_e$ (estimated), according to the method suggested by Herzberg (7). The moment of inertia is $9.475 \times 10^{-39} \text{ c cm}^2$.

Heat of Formation.
The equilibrium pressures for the reaction $\text{FeF}_2(\text{c}) + \text{H}_2(\text{g}) = \text{Fe}(\text{c}) + 2\text{HF}(\text{g})$ have been measured by K. Jellinek and A. Rudat, Z. anorg. allgem. Chem. 175, 281 (1928) at 773, 875 and 973°K. The enthalpy change (ΔH_f° 298.15) of the reaction was evaluated by the second and third law methods to be 27.19 and 39.08 kcal. mole⁻¹, respectively. Based on the third law value of ΔH_f° 298.15, the ΔF_f° 298.15 (FeF₂, c) was calculated to be -168.7 + 10 kcal. mole⁻¹. The drift in the third law values of ΔH_f° 298.15 was evaluated to be 13.3 ± 1.8 e.u.

Heat Capacity and Entropy.
The low temperature (11.35 - 307.50°K.) heat capacities were determined by E. Catalano and J. W. Stout, J. Chem. Phys. 23, 1803 (1955). The heat capacities above 307°K. were estimated by comparison with those of FeCl₂(c), MgCl₂(c) and MgF₂(c). The value of S_{298.15} was obtained from E. Catalano and J. W. Stout, loc. cit., in which a sharp maximum C_p of 17.8 cal. deg.⁻¹ mole⁻¹ at 78.35°K. was reported. The S_{298.15} value was based on S₁₅ = 0.039 e.u.

Melting Data.
T_m was estimated as 1100°C based on the data reported by W. Biltz and E. Rehlf, Z. anorg. allgem. Chem. 166, 363 (1927). The value of ΔH_m° was calculated using $\Delta S_m^\circ = 9$ e.u. which was assumed to be the same as the corresponding value for MgF₂(c).

Heat of Sublimation.
The value of ΔH_s° 298.15 was obtained from J. I. Margrave, "Research in Fluorine Chemistry", Progress Report No. 7, 1 January to 31 March 1965, William Marsh Rice University, Houston, Texas. See FeF₂(g) table for details.

$$\Delta H_f^{\circ} 298.15 = [21.951] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^{\circ} = [12.4] \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{\circ} = [53.64] \text{ kcal. mole}^{-1}$$

$$T_m^{\circ} = [1373]^{\circ}\text{K.}$$

$$T_b^{\circ} = [2110]^{\circ}\text{K.}$$

Heat of Formation.

The value of $\Delta H_f^{\circ} 298.15$ (FeF₂, l) was obtained from $\Delta H_f^{\circ} 298.15$ (FeF₂, c) by adding ΔH_m° and the difference between $H_m^{\circ} - H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity for FeF₂(l) was estimated by comparison with those for FeCl₂(c), MgCl₂(c), MgF₂(c), CaCl₂(c) and CaF₂(c). The C_p (FeF₂, l) value was assumed to be constant in the temperature range, 298.15 - 3000°K. The entropy ($S_{298.15}^{\circ}$) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See the FeF₂(c) table for details.

Vaporization Data.

T_b is calculated as the temperature at which the free energy change of the reaction $\text{FeF}_2(\text{l}) = \text{FeF}_2(\text{g})$ approaches zero. The difference between ΔH_f° for FeF₂(l) and FeF₂(g) at T_b is ΔH_v° .

Heat of Formation.

The rate of sublimation of FeF₂(c) was measured between 965 and 1149°K. by the Knudsen technique employing the high temperature magnetic mass spectrometer by John L. Margrave, "Research in Fluorine Chemistry", Progress Report No. 7, 1 January to 31 March 1965, William March Rice University, Houston, Texas. The only vapor species of importance is FeF₂(g). From the vapor pressure data the third law heat of sublimation (ΔH_f° 298.15) was reported as 75.6 ± 2.0 kcal. mole⁻¹. The sum of the values of ΔH_f° 298.15 and ΔH_f° 298.15 for FeF₂(c) is the ΔH_f° 298.15 (FeF₂ g).

Heat Capacity and Entropy.

The molecular structure was assumed to be linear. The Fe-F bond distance was estimated from that in FeF₂(c) reported by W. H. Baur, Acta Cryst. 11, 488 (1955). The vibrational frequencies, ω_j, and ω_j, were estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. 63, 111 (1963). The values of ω_j, electronic levels and quantum weights were estimated by comparison with those for FeCl₂(g). See FeCl₂(g) table for details. The moment of inertia is 2.04404 X 10⁻³⁹ g. cm.²

POTASSIUM BIFLUORIDE (KHF₂)

(CRYSTAL)

MOL. WT. = 78.108

$\Delta H_f^o = -220.74 \pm 0.35$ kcal. mole⁻¹
 ΔH_f^o 298.15 = -221.90 ± 0.35 kcal. mole⁻¹
 $\Delta H_c^o = 2.671 \pm 0.01$ kcal. mole⁻¹
 $\Delta H_m^o = 1.582 \pm 0.003$ kcal. mole⁻¹
 $S_{298.15}^o = 25.0 \pm 0.1$ cal. deg. mole⁻¹
 $T_c = 469.8^\circ K.$
 $T_m = 511.8^\circ K.$

Heat of Formation.

The heat of formation was obtained from the enthalpy of decomposition measurements of M. L. Davis and E. F. Westrum, J. Phys. Chem. 65, 339 (1961) who gave $\Delta H_d^{500} = 18.82 \pm 0.05$ kcal. mole⁻¹ and the heats of formation of HF(g) and KF(c) in conjunction with enthalpies at 500°K. from E. F. Westrum and K. S. Pitzer, J. Am. Chem. Soc. 71, 1940 (1949). A third law analysis of the decomposition vapor pressure by Westrum and Pitzer, loc. cit. did not agree with enthalpy of decomposition measurements, giving $\Delta H_d^{298} = 21.274 \pm 0.2$ kcal. mole⁻¹ as compared to Davis and Westrum's value at 298°K. of 21.505 ± 0.05 kcal. mole⁻¹. As the liquid vapor pressure data, which were not used, have a large trend in the third law heat of vaporization with temperature it was suspected that the pressure measurements were in error. This is borne out somewhat by a small trend in the values over the solid in the range 480-500°K.

Heat Capacity and Entropy.

Westrum and Pitzer, loc. cit., have measured the heat capacity from 16°K. to the melting point. Their data has been used to calculate the entropy at 298° using a T³ law extrapolation below 16°K., giving $S_{16}^o = 0.103$ e.u.

Melting and Transition Data.

The temperatures of melting and transition and the heats of melting and transition were taken from Davis and Westrum, loc. cit.

POTASSIUM BIFLUORIDE (KHF₂)

(LIQUID)

MOL. WT. = 78.108

S°_{298.15} = 32.3 cal. deg. mole⁻¹ ΔH_f^o 298.15 = -218.24 ± 0.35 kcal. mole⁻¹

T_m = 511.8°K. ΔH_m^o = 1.582 ± 0.003 kcal. mole⁻¹

T_{decomp.} = [751]°K.

Heat of Formation.

This was calculated from the heat of formation of the crystal, the heat of melting and H°_{511.8} - H°_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The entropy was determined from that of the crystal in a manner analogous to the heat of formation. The heat capacity just above the melting point was measured by E. F. Westrum and K. S. Pitzer, J. Am. Chem. Soc. 71, 1940 (1949) and was assumed constant above the melting point. A glass type transition was assumed at 341°K. below which the heat capacity is that of the solid.

Melting.

See table for crystal.

Decomposition.

The temperature of decomposition was estimated from the free energy cross-over and is the point where the HF(g) reaches 1 atm. It should be noted that the vapor pressures over the liquid of Westrum and Pitzer, loc. cit. are apparently in error, being high by roughly 12%. A 3rd law analysis at each vapor pressure point gave an almost constant heat of reaction in the solid region but in the liquid region the value changed abruptly with temperature. The only factors which were variable were the pressure and the liquid heat capacity, a trial change of 20% in the heat capacity produced an almost negligible change in the heat of reaction. Thus the vapor pressures over the liquid appear to be in error and the decomposition point of 702°K. obtained by extrapolating to 1 atmosphere is also in error.

F₂HK

Difluorosilane (SiH₂F₂)
 (Ideal Gas) Mol. Wt. = 68.106

MERCURY DIFLUORIDE (HgF₂) (Crystal)

Mol. Wt. = 238.61

 $\Delta H_f^\circ 298.15 = [-101.0 \pm 10.0] \text{ kcal. mole}^{-1}$ $\Delta G_f^\circ 298.15 = [27.800 \pm 2.0] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $T_m = 918^\circ \text{K}$ $\Delta H_m = [5.5 \pm 1.0] \text{ kcal. mole}^{-1}$

Heat of Formation. Estimated by comparison of the mercurous and mercuric halides.

Heat Capacity and Entropy. The heat capacity was assumed to be a linear function of temperature and was estimated to be 7.0 cal. deg.⁻¹ per atom at the melting point. The entropy was estimated by comparison with the other mercuric and mercurous halides and use of additive entropy constants for the halogens from K. K. Kelley (Private Communication, 1960).

Melting. T_m was given by O. Ruff and G. Behlau, Ber. 51, 1752 (1918). The heat of melting was from L. Brewer, paper 7, National Nuclear Energy Series A-198 "Thermodynamics" McGraw-Hill (1950).

Mercury Difluoride (HgF₂)

MERCURY DIFLUORIDE (HgF₂)
(Liquid)

Mol. Wt. = 238.61
ΔH_f^o 298.15 = [-96.772 ± 10.0] kcal. mole⁻¹
S_{298.15}^o = [32.083 ± 2.0] cal. deg.⁻¹ mole⁻¹
T_m = 918°K
ΔH_m = [5.5 ± 1.0] kcal. mole⁻¹
T_b = 920°K
ΔH_v = [22.0 ± 4.0] kcal. mole⁻¹

Heat of Formation. Calculated from ΔH_f^o (crystal).

Heat Capacity and Entropy. C_p was estimated by analogy with mercuric iodide and bromide. A glass type transition was assumed at 613°K below which the heat capacity was that of HgF₂(crystal). The entropy was calculated from S°(crystal) and the estimated ΔH_m and heat capacities of crystal and liquid.

Fusion and Vaporization. T_m was given by O. Ruff and G. Bahian, Ber. 51, 1752 (1918). T_b, ΔH_m, and ΔH_v were all taken from L. Brewer, paper 7, National Nuclear Energy Series 4-19B "Thermodynamics" McGraw-Hill (1950).

MOL. WT. = 238.61

(IDEAL GAS)

MERCURY DIFLUORIDE (HgF₂)

Point Group D_{∞h}

ΔH_f⁰ 298.15 = [-70.2 ± 10.0] kcal mole⁻¹ S_{298.15} = 63.545 cal deg⁻¹ mole⁻¹

Vibrational Levels and Multiplicities

ω, cm⁻¹
[600] (1)
[120] (2)
[593] (1)

Hg-F distance = [1.96] Å

Moment of Inertia = [12.118 × 10⁻³⁹] g cm² σ = 2

Heat of Formation

Estimated by comparison with the other gaseous mercuric halides and with the crystalline mercurous mercuric fluorides.

Heat Capacity and Entropy

Vibrational constants were estimated by analogy with the other mercuric halides and the mercurous halides. The bond length was estimated by assuming the mercurous bond to be 0.965 of the mercuric bond by analogy with the mercury chlorides.

MERCURY MONOFLUORIDE, DIMERIC (Hg_2F_2) (Crystall)

Mol. Wt. = 439.22
 $\Delta H_f^{298.15} = [-116.0 \pm 3.0]$ kcal. mole⁻¹
 $S_{298.15}^{298.15} = [38.4 \pm 2.0]$ cal. deg.⁻¹ mole⁻¹
 $T_{\text{sub}} = [848]^\circ\text{K}$ (decomp.)

Heat of Formation. A value of $\Delta H_f^{298.15}$ was obtained from the cell measurements of G. G. Koerber and T. de Vries, J. Amer. Chem. Soc. 71, 5000 (1949). This was combined with ΔS_f^{298} from the estimated entropy.

Heat Capacity and Entropy. The heat capacity was estimated by comparison with mercurous chloride. The entropy was estimated by comparison with the other mercurous and mercuric halides and use of additive entropy constants for the halogens from K. K. Kelley (Private Communication, 1960).

Sublimation. Sublimation with decomposition to $\text{Hg}(g)$ and $\text{HgF}_2(g)$ was assumed at 848°K from the free energy change of the reaction.

{500} (1)

The heat of formation is estimated from three calculated values. The methods of calculation are described as follows. In a manner analogous to LiF₂(g), the first reaction considered is KF(g) + F⁻(g) = KF₂⁻(g) and the ΔH_f^o298(KF₂⁻, g) is evaluated to be between 0 and 1/2(-50) = -25 kcal/mol (see LiF₂⁻(g) table for details), yielding from JANAF Tables. The ΔH_f^o298 values for the other species involved are taken

The second reaction employed for estimation is K₂F₂(g) = KF₂⁻(g) + K⁺(g). The enthalpy change of this reaction is calculated as ΔH_r^o298 = 1/2(50.0) + 138.8 = 163.8 kcal/mol where the KF₂⁻ ion is considered to be converted from K₂F₂(g) by breaking one of the two dimer association bonds (ΔH_r^o298 = 50.0 kcal/mol) and one K⁺-F⁻ ionic bond (ΔH_r^o298 = 138.8 kcal/mol). Using ΔH_f^o298 = -206.2 and 122.9 kcal/mol for K₂F₂(g) and K⁺(g), we obtain the heat of formation for KF₂⁻(g) as -165 kcal/mol.

Based on an assumption that the electron affinity of KF₂⁻(g) is similar to that of F (see LiF₂⁻(g) table for details), i.e. ΔH_r^o = 83.5 kcal/mol (1) for the reaction KF₂⁻(g) = KF₂(g) + e⁻(g), we derive ΔH_f^o298(KF₂⁻, g) = -167.7 kcal/mol. The ΔH_f^o298 for KF₂(g) is calculated as -84.2 kcal/mol from the value ΔH_r^o298 = 143.3 kcal/mol for the reaction K₂F₂(g) = KF₂(g) + K(g) where the ΔH_r^o298 value is calculated as the sum of two enthalpy changes, i.e. half of the heat of dimer dissociation into two monomers or 1/2(50.0) = 25.0 kcal/mol, and the heat of dissociation of KF(g) or 118.3 kcal/mol. The value of ΔH_f^o298 for KF₂⁻(g) is tentatively adopted as -166 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion given by Walsh (2) that molecules with not more than 16 valency electrons are linear in their ground states. The K-F bond distance is taken to be the same as that of KF(g) reported by Veazey and Gordy (3). The vibrational frequencies are estimated from the vibrational frequency of KF(g) using the method suggested by Herzberg (4). The moment of inertia is 2.971 × 10⁻³⁸ g cm². The enthalpy at 0°K is -3.293 kcal/mol.

Heat of Formation

The equilibrium constants (K_c) for the reaction $K_2F_2(g) = 2KF(g)$, in the temperature range 978-1052°K, were determined by Eisenstadt, Rothberg, and Kusch (2). Although the reported absolute values of the vapor pressures of $KF(g)$ are not adopted for evaluation, the reported K_c values are used to calculate the enthalpy change (ΔH_{298}°) for the above reaction. The second law and third law values of ΔH_{298}° are derived as 51.0 ± 1.6 and 50.0 kcal/mol , respectively. Based on the third law ΔH_{298}° and $\Delta H_{298}^\circ(KF, g) = -78.1 \text{ kcal/mol}$, we obtain $\Delta H_{298}^\circ = -206.2 \text{ kcal/mol}$ for $K_2F_2(g)$ which is tentatively adopted.

Heat Capacity and Enthalpy

The molecular structure and K-F bond distance were determined by Akishin and Rambidi (2), using electron diffraction with sector microphotometry. The bond angles are estimated by comparison with other alkali halide dimers. The vibrational frequencies are taken from Berkowitz (3) which were calculated based on an ionic model. The three principal moments of inertia are: $I_A = 3.1423 \times 10^{-38}$, $I_B = 1.5267 \times 10^{-38}$, and $I_C = 4.6690 \times 10^{-38} \text{ g cm}^2$.

Heat of Formation

Due to lack of thermal data, the heat of formation for $LiF_2^-(g)$ is arbitrarily selected from the following three estimated values. For the reaction (1) $LiF(g) + F^-(g) = LiF_2^-(g)$, we expect the enthalpy change would be between 0 to -31 kcal/mol. Comparison with the other molecules like CO_2 , BO_2 , BeF_2 , etc. having 16 valence electrons leads us to assume that the isoelectronic molecule LiF_2^- should also be quite stable. This indicates that reaction (1) is favorable or ΔH_{298}^0 is negative. However, the $Li-F$ bond strength is expected to be weaker than half of the two ionic bonds between Li^+ and F^- in LiF_2 molecule (see LiF_2 (g) table for the molecular structure). In other words, the ΔH_{298}^0 value of reaction (1) is less negative than half of the heat of dimerization (-62.4 kcal/mol). Incorporating $\Delta H_{298}^0 = 0$ and -31 kcal/mol , respectively, for reaction (1), with $\Delta H_{298}^0 = -81.45$ and -62.2 kcal/mol for $LiF(g)$ and $F^-(g)$, we derived the corresponding values for $\Delta H_{298}^0(LiF_2^-, g)$ as -144 and -175 kcal/mol , which are the upper and lower limits.

The electron affinities of Li and F atoms are reported as 0.7 and 3.448 eV, respectively, by Beckett and Cassidy (1). From this data we estimate that the electron affinity of $LiF_2(g)$ should be closer to that of F atom than to that of Li. Assuming ΔH_{298}^0 = electron affinity of F atom = 83.5 kcal/mol for the reaction $LiF_2^-(g) = LiF_2(g) + e^-(g)$, we obtain the heat of formation for $LiF_2^-(g)$ as -177.3 kcal/mol . The $\Delta H_{298}^0(LiF_2, g)$ used for calculation is derived from an estimated $\Delta H_{298}^0 = 169.9 \text{ kcal/mol}$ for the decomposition of LiF dimer or $Li_2F_2(g) = LiF_2(g) + Li(g)$ as the sum of two enthalpy changes, namely, half of the heat of dissociation of the dimer and the heat of dissociation of the monomer.

The third estimated value for the heat of formation of $LiF_2^-(g)$ is calculated as follows. Based on the two heats of reaction, i.e. $\Delta H_{298}^0 = 62.4 \text{ kcal/mol}$ for $Li_2F_2(g) = LiF(g) + LiF(g)$, and $\Delta H_{298}^0 = 183.5 \text{ kcal/mol}$ for $LiF(g) + F^-(g) = LiF_2^-(g)$, we assume the enthalpy change of the reaction $Li_2F_2(g) = LiF_2(g) + Li^+(g) + F^-(g)$ to be $1/2(62.4) + 183.5 = 714.7 \text{ kcal/mol}$. In other words, we consider the $LiF_2^-(g)$ molecule is formed by breaking half of the dimer dissociation bonds and one monomer dissociation bond to produce two ions. Using $\Delta H_{298}^0 = -225.33$ and 164.24 kcal/mol for $Li_2F_2(g)$ and $Li^+(g)$, we evaluate $\Delta H_{298}^0(LiF_2^-, g) = -174.9 \text{ kcal/mol}$.

From the above three estimated values, we tentatively choose $\Delta H_{298}^0(LiF_2^-, g)$ as $-170 \pm 15 \text{ kcal/mol}$.

Heat Capacity and Entropy

According to A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953), molecules with not more than 16 valence electrons are linear in their ground states. Since $LiF_2^-(g)$ has 16 valence electrons, we assume its molecular structure is linear. The $Li-F$ bond distance is estimated by comparison with that of $LiF(g)$ reported by Wharton et al. (2). The vibrational frequencies are estimated from those of the isoelectronic gaseous molecules, CO_2 and BeF_2 . The moment of inertia is $1.555 \times 10^{-38} \text{ g cm}^2$. The enthalpy at 0°K is -2.653 kcal/mol .

Dec. 31, 1960; June 30, 1964; Mar. 31, 1966

S_{298.15} = 13.68 ± 0.07 cal. deg.⁻¹ mole⁻¹
T_m = 1536°K.
ΔH_f^o 0 = -267.8 ± 0.3 kcal. mole⁻¹
ΔH_f^o 298.15 = -268.7 ± 0.3 kcal. mole⁻¹
ΔH_m^o = 13.90 kcal. mole⁻¹
ΔH_m^o 298.15 = 95.5 ± 1.5 kcal. mole⁻¹

Heat of Formation.

The value of ΔH_f^o 298.15 for MgF₂(c) was obtained from E. Rudzitis and W. N. Hubbard, Argonne National Laboratory, Argonne, Illinois, private communication, dated June 18, 1964. This value was determined by fluorine bomb calorimetry which is considered as comparatively the best method available at the present time. The heats of reaction involving MgF₂(c) were measured by many early investigators. However, the ΔH_f^o 298.15(MgF₂, c) values derived are in reasonable agreement. The results are presented as follows.

Investigator	Chemical Reaction	ΔH _f ^o 298.15, kcal. mole ⁻¹	ΔH _f ^o 298.15, kcal. mole ⁻¹
Domange (1)	MgF ₂ (c) + H ₂ O(g) → 2HF(g) + MgO(c)	+51.76 ± 1.2 (1)	-267.3 ± 1.3
Wartenberg (2)	Mg(c) + 2(HF·80H ₂ O) → MgF ₂ (c) + H ₂ (g) + 160H ₂ O(l)	-109.5 ± 0.7	-262.1 ± 0.8
Torgeson, et al. (3)	Mg(OH) ₂ (c) + 2HF(sol.) → MgF ₂ (c) + 2H ₂ O(l)	-29.09	-266.5 ± 0.8
Gross, et al. (4)	Mg(c) + PbF ₂ (c) → MgF ₂ (c) + Pb(c)	-109.5 ± 1.5	-269.1 ± 1.8
(1) L. Domange, Ann. chim. phys. 7(11)225 (1937). The ΔH _f ^o value was calculated by the third law method.			
(2) H. V. Wartenberg, Z. anorg. allgem. Chem. 249, 100 (1942).			
(3) D. R. Torgeson and T. G. Sahan, J. Am. Chem. Soc. 70, 2156 (1948).			
(4) P. Gross, C. Hayman and D. L. Levi, Trans. Faraday Soc. 50, 477 (1954).			

Heat Capacity and Entropy.

The low temperature heat capacities, 54.22-296.5°K., were measured by S. S. Todd, J. Am. Chem. Soc. 71, 4115 (1949). The high temperature heat capacities, 298-1536°K., were obtained from the heat content measurements determined by E. F. Naylor, J. Am. Chem. Soc. 67, 150 (1945). These two sets of data were joined smoothly at 298°K. S_{298.15} was obtained from C_p data reported by S. S. Todd, loc. cit., using S_{298.15} (extrap.) = 0.537 cal. deg.⁻¹ mole⁻¹.

Melting Data.

T_m and ΔH_m^o were taken from E. F. Naylor, loc. cit.

Heat of Sublimation.

The vapor pressure of MgF₂(c) has been measured by seven investigators. Using the reported data, the respective ΔH_m^o 298.15 for MgF₂(c) were calculated (see MgF₂(c) table for detail). The adopted value was selected to be 95.5 ± 1.5 kcal. mole⁻¹.

Heat of Formation.

ΔH_f° 298.15(l) was obtained from ΔH_f° 298.15(c) by adding ΔH_m° and the difference between H_m°-H_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

Heat capacity (169-1800°K.) was reported by B. F. Naylor, J. Am. Chem. Soc. 67, 150 (1945). The same value was used for other temperatures. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m and ΔH_m° were obtained from B. F. Naylor, Loc. Cit.

Vaporization Data.

T_b was obtained from equilibrium calculation between the species MgF₂(l), MgF₂(g), and (MgF₂)₂(g), i.e., the temperature at which the sum of the partial pressures of MgF₂(g) and (MgF₂)₂(g) equals one atmosphere.

From the difference between the heats of formation of MgF₂(l) and MgF₂(g) at the boiling point, the heat of vaporization was calculated. At the boiling point the amount of dimeric species is negligible in comparison with that of the monomeric species.

MAGNESIUM DIFLUORIDE (MgF₂)

(IDEAL GAS)

Point Group C_{2v}
 $S_{298.15}^0 = 61.734 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 Ground State Quantum Weight = [1]

$\Delta H_f^0 = -172.0 \pm 1.5 \text{ kcal. mole}^{-1}$
 $\Delta F_f^0 = -173.2 \pm 1.5 \text{ kcal. mole}^{-1}$

Vibrational Frequencies and Degeneracies

ω , cm ⁻¹
478 (1)
241 (1)
834 (1)

Bond Distances: Mg-F = $1.77 \pm 0.02 \text{ \AA}$
 Bond Angle: F-Mg-F = $150 \pm 5^\circ$
 Product of the Moments of Inertia: $I_A I_B I_C = 1.80532 \times 10^{-115} \text{ g.}^3 \text{ cm.}^6$

 $\sigma^* = 2$

Heat of Formation.

The vapor pressure of MgF₂(g) over MgF₂(c) and MgF₂(l) has been measured by many investigators using different methods. Based on the reported vapor pressure data, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented as follows.

Investigator	Temperature, °K.	Method*	Second Law Value	Third Law Value	Drift
Ruff and Boucher ¹	1934 - 2129	a	99.49 ± 2.56	96.19	-1.66 ± 1.31
Quentner ²	1284 - 1550	b	95.06 ± 0.50	95.64	0.45 ± 0.53
Hammer ³	1451 - 1533	b	93.68 ± 2.67	96.21	1.62 ± 1.79
	1568 - 1613	b	94.17 ± 6.40	96.21	1.26 ± 4.16
	1413 - 1518	c	96.75 ± 2.99	96.19	0.22 ± 2.08
	1539 - 1614	c	96.81 ± 4.35	96.09	-0.51 ± 2.74
Berkowitz and Marquart ⁴	1450	c	80.72 ± 1.11	91.58	7.75 ± 0.80
Farber, et al. ⁵	1275 - 1513	c	91.80 ± 1.11	93.40	1.12 ± 0.78
Hildenbrand, et al. ⁶	1544 - 1604	c	94.49 ± 5.00	95.95	-0.39 ± 3.17
	1425 - 1533	c	104.79 ± 1.00	95.75	-6.14 ± 0.65
	1540 - 1608	c	102.81	95.49	-4.65
Margrave, et al. ⁷	1200 - 1550	-	94.0	95.07	1.69 ± 0.08
	1241 - 1492	b	95.77 ± 2.5	95.07	1.69 ± 0.08

*a = Manometric method; b = Knudsen effusion method; and c = Torsion effusion method

1 O. Ruff and L. LeBoucher, Z. anorg. allgem. Chem. 219, 376 (1934).

2 K. O. Quentner, Unstet. Ber. 31, 9 (1956).

3 R. R. Hammer, Ph.D. Thesis, University of California, 1961. Also see R. R. Hammer and J. A. Pask, J. Am. Chem. Soc. 83, 264 (1961).

4 J. Berkowitz and J. R. Marquart, J. Chem. Phys. 37, 1853 (1962). The value, 91.36 kcal. mole⁻¹, was converted from the reported value 86 kcal. mole⁻¹ at 1350°K.5 H. A. Greenbaum, H. C. Ho, R. Kong and M. Farber, J. Phys. Chem. 69, 985 (1964), whose reported ΔH_f 238.15 kcal. mole⁻¹ was derived using different values of free energy functions for MgF₂(c) and MgF₂(g) from those used here.

6 Values of data were obtained from D. L. Hildenbrand, et al., J. Phys. Chem. 68, 1155 (1964), and D. L. Hildenbrand, et al., J. Phys. Chem. 68, 1155 (1964).

7 J. W. Green, G. D. Blue, T. C. Ehler and J. L. Margrave, J. Chem. Phys. 41, 2245 (1964).

When vapor pressure data were determined above melting point, 1530°K., the heat of sublimation was derived from the heat of vaporization obtained incorporating heat of melting. All data were carefully examined and some inconsistent vapor pressure points were discarded. The heat value of ΔH_f 238.15 for MgF₂(c) was selected as 95.5 ± 1.5 kcal. mole⁻¹. The heat of formation for MgF₂(g) was calculated from the heats of formation and sublimation for MgF₂(c).

Heat Capacity and Entropy.

The molecular structure of MgF₂(g) has been reported to be linear by A. Büchler, J. L. Stauffer and W. Klemperer, Interim Technical Report No. 7, June 30, 1964, A. D. Little, Inc., and bent by M. J. Linevsky, First Quarterly Report, Nov. 1, 1963 - Jan. 31, 1964, General Electric Company. An intensive investigation of the matrix spectrum of MgF₂(g) has been made recently by D. E. Mann and O. V. Calder, National Bureau of Standards Report 8919, July 1, 1965. The final results were presented by D. E. Mann at the ICRG Working Group on Thermochemistry meeting on Mar. 17, 1966.The vibrational frequencies, bent structure and bond angle were confirmed by use of isotopic substitution, and were adopted here. The Mg-F bond distance was reported by P. A. Aikshin, V. P. Spiridonov, O. A. Sobolev and V. A. Naumov, Zh. Fiz. Khim. 31, 463 (1957). The three principal moments of inertia are: I_A = 5.1660 × 10⁻⁴⁰, I_B = 1.8442 × 10⁻⁵⁸ and I_C = 1.8959 × 10⁻⁵⁹ g. cm.²F₂Mg

MOL. WT. = 62.3088

Dec. 31, 1962; Mar. 31, 1964

C. B. Colburn and P. A. Johnson, J. Chem. Phys. **33**, 1869 (1960), report the study of the dissociation reaction N₂F₄(g) = 2NF₂(g) by two independent methods: (a) measurement of the pressure variation with temperature at constant volume and (b) a spectrophotometric method based on the temperature dependence of the ultraviolet absorption of the NF₂ radical. The authors give a more detailed account of their data in J. Am. Chem. Soc. **83**, 3043 (1961). The contents of these articles indicate that 2NF₂(g) should read 2NF₂(g) in the above reaction. The first method gave a value of 19.85 kcal. mole⁻¹ for the heat of dissociation in the temperature range 373 to 423°K, which corresponds to 19.87 kcal. mole⁻¹ at 298°K. From their ΔH and ΔS data, ΔP was calculated and used in a third law evaluation of the heat of dissociation. The ΔH₂₉₈ so calculated showed an increasing trend with increasing temperature; the average value was 22.87 kcal. mole⁻¹ which is not in agreement with their value of 19.87 kcal. mole⁻¹. The spectrophotometric value of 21.7 kcal. mole⁻¹ at 298°K. was obtained from the integrated Van't Hoff equation.

L. H. Piette, P. A. Johnson, K. A. Boomer and C. B. Colburn, J. Chem. Phys. **35**, 1481 (1961), studied the temperature dependence of the EPR spectrum of the NF₂ radical. They obtained a second law value of 19.3 kcal. mole⁻¹ for the heat of dissociation. This value, however, depends upon the degree of dissociation of N₂F₄ which they calculated from the (dP/dT) measurements of Colburn and Johnson. Any error in the (dP/dT) measurements would manifest itself in like manner here.

H. E. Doornbos and B. R. Loy, J. Chem. Phys. **39**, 2393 (1963), investigated the ESR spectrum of the N₂F₄-NF₂ equilibrium from which they calculated a second law value of 19.8 kcal. mole⁻¹ for the heat of dissociation. They report that at 25°C. and 13 atm. N₂F₄ is 0.02% dissociated in the vapor phase. A third law calculation using this datum and the relationship $K_p = (4\alpha^2/\lambda - \alpha^2)P_0$, where α is the degree of dissociation of N₂F₄ and P₀ is the total pressure, gave a heat of dissociation of 21.79 kcal. mole⁻¹ at 298°K.; this is not in agreement with their second law value.

J. T. Herron and V. H. Dibel, J. Research Natl. Bur. Standards **65A**, 405 (1961), report thermal dissociation data for N₂F₄. From their data they calculate a second law value of 21.5 kcal. mole⁻¹ for the heat of dissociation of N₂F₄. A second and third law evaluation of their data was performed in the Dow Thermal Laboratory. It was found that if the k factor, relating their measured ion abundances to partial pressures, was taken as 4.72 X 10⁻⁹, a third law value was obtained that showed slight scatter but no temperature dependence. Excluding those points that showed scatter, the third law heat of dissociation at 298°K. was 22.27 kcal. mole⁻¹. A second law plot gave a heat value of 22.23 kcal. mole⁻¹ at an average temperature of 400°K. or 22.25 kcal. mole⁻¹ at 298°K. Those points that deviated from the chosen straight line in the second law plot showed corresponding deviations in the third law calculation. Those points lying on the second law slope gave a constant third law value.

The heat of dissociation for N₂F₄(g) = 2NF₂(g) was taken to be 22.26 kcal. mole⁻¹. Utilizing the heat of formation of N₂F₄(g) (see N₂F₄ table), the heat of formation of the difluoramine radical becomes 10.1 ± 2.0 kcal. mole⁻¹. All values for the heat of dissociation fall within the limits of error assigned to the heat of formation of NF₂.

Heat Capacity and Entropy.

See table on tetrafluorohydrazine (N₂F₄) (ideal gas) for writup.

σ = 2

Heat of Formation.

The heat of formation was derived from the heat of reaction $N_2F_2(g) + 8/3 NH_3(g) = 2NH_4F(c) + 4/3 N_2(g)$ which was measured calorimetrically by G. T. Armstrong and S. Marantz¹. There are two isomers, the trans and the active form of difluorodiazine. The heats of formation were determined to be 19.4 and 16.4 kcal. mole⁻¹ for the trans and the active isomers respectively. The active form of N₂F₂ has been interpreted here as the cis isomer which will be discussed later. The heat of isomerization has also been reported as 3.0 kcal. mole⁻¹ by Armstrong and Marantz. The value, ΔH_f° 298 (cis N₂F₂, g) = 16.4 kcal. mole⁻¹, is adopted in the tabulation.

A. V. Pankratov et al.² have measured the enthalpy of reaction $N_2F_2(g) + 3KI = 2KF + N_2 + KI_3$ in acidic solution (pH = 3), and reported ΔH_f° 298 (active N₂F₂, g) = 25.3 ± 2.0 kcal. mole⁻¹.

The "heat of isomerization" has been reported as 27.5 ± 5.0 kcal. mole⁻¹ by C. B. Colburn et al.⁹. The derivation of this value is unknown. The authors observed three values of the equilibrium constant for the isomerization reaction. Third law analysis of their data gives ΔH_f° 298 = 2.52 ± 0.05 kcal. mole⁻¹ for the reaction cis N₂F₂(g) → trans N₂F₂(g) which is in good agreement with Armstrong and Sidney's data.

Heat Capacity and Entropy.

Although the infrared spectrum^{7,8} of the active form of N₂F₂(g) has been interpreted as favoring the 1,1-difluorodiazine over the cis-configuration^{3,4}, n.m.r.⁵ and microwave studies definitely indicate the latter. The vibrational frequencies⁷ previously assigned to the 1,1-difluorodiazine have been adopted here for the cis isomer. The selected bond distances and angle were taken from the isotopic nitrogen microwave studies⁶. The principal moments of inertia were: I_A = 4.2438 X 10⁻³⁹, I_B = 10.5129 X 10⁻³⁹ and I_C = 14.7567 X 10⁻³⁹ g. cm.². See the trans N₂F₂(g) table for the comparison of the different physical properties between trans and cis isomers.

Heat of Formation.

G. T. Armstrong and S. Marentz, J. Chem. Phys. **39**, 169 (1963) have measured calorimetrically the enthalpy of reaction $N_2F_2(g) + 8/5 NH_3(g) = 2NH_4^+(c) + 4/5 N_2(g)$, and reported ΔH_f° 298 (trans N₂F₂, g) = 19.4 ± 1.2 kcal. mole⁻¹ which is adopted in this tabulation.

Heat Capacity and Entropy.

The bond distances and bond angle were obtained from S. H. Bauer, J. Am. Chem. Soc. **69**, 3104 (1947), by electron diffraction. The fundamental vibrational frequencies were obtained from R. H. Sanborn, J. Chem. Phys. **33**, 1855 (1960) by infrared spectroscopy. The three principal moments of inertia are $I_A = 0.919 \times 10^{-39}$, $I_B = 21.2433 \times 10^{-39}$ and $I_C = 22.1623 \times 10^{-39}$ g. cm.²

As pointed out by R. Ettinger, F. A. Johnson and C. B. Colburn, J. Chem. Phys. **34**, 2187 (1961), the trans N₂F₂ is the less active isomer which is different from the active isomer by its (1) vapor pressure (2) boiling point (3) heat of vaporization (4) critical temperature (5) melting point (6) mass spectral cracking pattern (7) NMR spectrum (8) infrared spectrum (9) heat of isomerization (10) reactivity with mercury and glass.

Bond Angle: F-Na-F = [180°]

Rotational Constant: B₀ = [0.119] cm⁻¹

Heat of Formation

The heat of formation for NaF₂⁻(g) is estimated from three calculated values. The methods of calculation are described as follows. The first reaction we take into consideration is NaF(g) + F⁻(g) + Na₂⁻(g). In a manner analogous to LiF₂⁻(g) molecule (see LiF₂⁻(g) table for details), we assume NaF₂⁻(g) is stable and ΔH_F²⁹⁸ for the reaction NaF(g) + F⁻(g) = NaF₂⁻(g) is somewhere between 0 to 1/2(-64) = -32 kcal/mol where the value -56 kcal/mol is the heat of dimerization. Based on ΔH_F²⁹⁸ = 0 and -28 kcal/mol, respectively, with JANAF ΔH_F²⁹⁸ values for the species involved, we obtain ΔH_F²⁹⁸(NaF₂⁻, g) = -132 and -164 kcal/mol as the upper and lower limits.

The heat of formation, calculated based on the reaction NaF₂⁻(g) = NaF₂(g) + e⁻(g), is -165.8 kcal/mol, using ΔH_F²⁹⁸ and ΔH_F²⁹⁸(NaF₂, g) estimated as 83.5 and -82.3 kcal/mol, respectively. The ΔH_F²⁹⁸ value is obtained from an assumption that the enthalpy change for removing an electron from NaF₂⁻(g) is comparable to that from F⁻(g). Due to the fact that the Na atom has smaller electronegativity (0.9) than that of the F atom (4.0), we expect that there is less possibility that the electron will associate with Na atom in the NaF₂⁻ molecule. Therefore we adopt the electron affinity of F(g) reported by H. O. Pritchard, Chem. Rev. 52, 529 (1953), or ΔH_F²⁹⁸ = 83.5 kcal/mol for the reaction F⁻(g) = F(g) + e⁻(g) as the ΔH_F²⁹⁸ for NaF₂⁻(g) = NaF₂(g) + e⁻(g). The value of ΔH_F²⁹⁸ for NaF₂(g) is calculated using the enthalpy change for the reaction NaF₂(g) = NaF₂⁻(g) + Na(g) as 145.8 kcal/mol which is derived from the sum of two enthalpy changes, namely, half of the ΔH_F²⁹⁸ value for the dimer dissociation reaction Na₂F₂(g) = 2NaF(g), and the ΔH_F²⁹⁸ for the monomer dissociation reaction NaF(g) = Na(g) + F(g).

Employing ΔH_F²⁹⁸ = 83.5 kcal/mol for NaF₂(g) and 153.0 kcal/mol for NaF₂⁻(g) = Na⁺(g) + F⁻(g), we estimate ΔH_F²⁹⁸ = 1/2(83.5) + 153.0 = 184.7 kcal/mol for the reaction Na₂F₂(g) = NaF₂(g) + Na⁺(g), which leads to ΔH_F²⁹⁸ = 183.4 kcal/mol for NaF₂⁻(g). For all calculations the ΔH_F²⁹⁸ values of the chemical species involved are taken from JANAF Thermochemical Tables.

The value of ΔH_F²⁹⁸ for NaF₂⁻(g) is tentatively adopted as -160 ± 10 kcal/mol.

Heat Capacity and Entropy

The molecular structure is assumed to be linear, according to the suggestion by A. D. Walsh, J. Chem. Soc. 1953, 2266 (1953) that molecules with not more than 16 valence electrons are linear in their ground state. The Na-F bond distance is estimated by comparison with that of NaF(g) reported by S. E. Veazy and W. Gordy, Phys. Rev. 138, A1303 (1965). The vibrational frequencies are estimated from those for the isoelectronic molecule SiO₂(g). The moment of inertia is 2.380 × 10⁻³⁸ gm². The enthalpy at 0°K is -3.117 kcal/mol.

Heat of Formation

Although the absolute values of the vapor pressure measurements are not used for evaluation, the ratios of the numbers of dimeric and monomeric NaF molecules that effuse from the oven at the temperatures 1115 - 1191°K determined by Eisenstadt, Rothberg, and Kusch (1) by use of the electron-beam velocity-selector method are used. Based on the reported equilibrium data we evaluate the enthalpy change of the reaction $(A) \text{ Na}_2\text{F}_2(g) = 2\text{NaF}(g)$ by the second and third law methods. The results are presented in the table below.

Porter and Schoonmaker (2) analyzed the vapor effusing from a Knudsen cell at 1121°K mass spectrometrically and derived the partial pressures of NaF(g) and Na₂F₂(g) at that temperature. Using these reported partial pressures we calculate, by the third law method, the value $\Delta H_{298}^\circ = 64.1 \text{ kcal/mol}$ for reaction (A).

Sidorov et al. (3) studied the NaF - ZrF₄ system by the mass spectrometric method and derived the partial pressures of NaF(g) and Na₂F₂(g) as a function of composition and temperature. Employing the data points reported at 1074° and 1167°K we obtain the third law value $\Delta H_{298}^\circ = 62.0 \pm 1.6 \text{ kcal/mol}$ for the same reaction.

The ΔH_{298}° (Na₂F₂, g) is calculated based on the adopted third law value $\Delta H_{298}^\circ = 63.5 \text{ kcal/mol}$ for the reaction $\text{Na}_2\text{F}_2(g) = 2\text{NaF}(g)$, using ΔH_{298}° (NaF, g) = -69.5 kcal/mol. Brewer and Brackett (3) reported $\Delta H_{1000}^\circ = 56.9 \text{ kcal/mol}$ for the above reaction. According to our tables the ΔH_{1000}° value is 62.5 kcal/mol.

Heat Capacity and Entropy

The Na₂F₂ molecule is assumed to have a rhombic structure with D_{2h} (h) symmetry (4, 5). The Na-F bond distance is reported by Akishin and Rambidi (5), who studied the molecular structure of alkali halide vapors by electron diffraction with sector microphotometry. The bond angle is estimated by comparison with those of the other alkali halides. Berkowitz (4, 6) has calculated the vibration frequencies of Na₂F₂ based on an ionic model. By comparison of the calculated frequencies of Li₂F₂ (g) with those of the observed ones (see Li₂F₂(g) table for details) we reestimate the vibrational frequencies for Na₂F₂(g) to be higher than the ones reported by Berkowitz (5). Bauer et al. (7) used a pseudo-electrostatic model, similar to the one suggested by O'Konski and Higuchi (8), to calculate the entropies of dimerization for a number of gaseous alkali halides and estimated the six vibrational frequencies as 477, 318, 291, 477, 291, and 291 cm⁻¹. Bauer et al. calculated $\Delta S_{1146}^\circ = -32.5 \text{ eu}$ for the reaction $2\text{NaF}(g) = \text{Na}_2\text{F}_2(g)$, in reasonable agreement with the value -33.5 eu which is derived using JANAF Silus values for NaF(g) and Na₂F₂(g).

The three principal moments of inertia are: $I_A = 1.399 \times 10^{-38}$, $I_B = 1.422 \times 10^{-38}$, and $I_C = 2.821 \times 10^{-38} \text{ g cm}^2$.

Vibrational Frequencies and Degeneracies

 ω_e, cm^{-1}

928 (1)

461 (1)

831 (1)

Bond Distance: F-O = 1.412 Å

Bond Angle: F-O-F = 103°10'

Product of the Moments of Inertia: $I_A I_B I_C = 1.01936 \times 10^{-115} \text{ g cm}^2$ $\sigma = 2$

Heat of Formation

King and Armstrong (1) have established the heat of formation with a series of reactions in a flame calorimeter. They burned F₂O in hydrogen to give HF aqueous, in addition they burned F₂ in hydrogen so that the heat of formation, 5.86 kcal/mol, is directly obtainable. This value is in good agreement with the recalculated values (1) from Wartenberg and Klinkott (2), 5.7 ± 2 kcal/mol, and Ruff and Menzel (3), 4.7 ± 2 kcal/mol but differs from that of Bisbee et al. (4), -4.06 ± 2.2 kcal/mol. There were several factors in the experiments of Bisbee that might cause a too negative heat of formation and we choose to adopt the definitive value of 5.86 kcal/mol reported by King and Armstrong.

Heat Capacity and Entropy

The structural parameters are those reported by Pierce et al. (5) for the average ground state molecule from the microwave spectrum. Earlier measurements of Hilton et al. (6) disagree but according to Pierce et al. (7) the line assignments used by Hilton are incorrect. The vibrational frequencies were reported by Jones et al. (8), several other investigators report similar values (9, 10, 11). Nebgen et al. (12) have obtained the anharmonic constants for the three vibrations. Individual moments of inertia are $I_A = 1.4396 \times 10^{-39}$, $I_B = 7.7255 \times 10^{-39}$ and $I_C = 9.1651 \times 10^{-39} \text{ g cm}^2$.

Dec. 31, 1960, Sept. 30, 1965

Thionyl Difluoride (SO₂F₂)

(Ideal Gas) MOL. WT. = 86.0602

Point Group C_{2v}
 $\Delta H_f^o = 66.965 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o = [-134 \pm 10] \text{ kcal. mole}^{-1}$
 $\Delta H_f^o = [-135 \pm 10] \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight = [1]

Vibrational Frequencies and Degeneracies	ω , cm. ⁻¹	ω , cm. ⁻¹
	1308 (1)	395 (1)
	801 (1)	721 (1)
	526 (1)	326 (1)

Bond Distances: O-S = 1.412 Å S-F = 1.585 Å
 Bond Angle: O-S-F = 106° 49' F-S-F = 92° 49'
 Product of the Moments of Inertia: I_AI_BI_C = 1.65545 X 10⁻¹¹⁴ g.³ cm.⁶
 $\sigma = 1$

Heat of Formation.

From the enthalpy change, $\Delta H_f^o = 131.03 \text{ kcal. mole}^{-1}$, for the reaction $\text{SO}_2(\text{g}) + \text{O}(\text{g})$, the value of ΔH_f^o for $\text{SO}_2(\text{g})$ was calculated to be -133.5 kcal. mole⁻¹, using $\Delta H_f^o = -203.0$ and 59.56 kcal. mole⁻¹ for $\text{SO}_2(\text{g})$ and $\text{O}(\text{g})$, respectively. The value of ΔH_f^o for $\text{SO}_2(\text{g})$ was assumed to be the same as that for the reaction $\text{SO}_2(\text{g}) = \text{SO}(\text{g}) + \text{O}(\text{g})$ which was calculated based on $\Delta H_f^o = -70.95$, 0.52 and 59.56 kcal. mole⁻¹ for $\text{SO}_2(\text{g})$, $\text{SO}(\text{g})$ and $\text{O}(\text{g})$, respectively. Using $\Delta H_f^o = 127.86 \text{ kcal. mole}^{-1}$ for the reaction $\text{SO}_2(\text{g}) = \text{SO}_2(\text{g}) + \text{O}(\text{g})$, the value of ΔH_f^o for $\text{SO}_2(\text{g})$ was calculated to be -136.7 kcal. mole⁻¹ where the ΔH_f^o for $\text{SO}_2(\text{g})$ was assumed to be the same as the S-O bond energy in $\text{SO}_2(\text{g})$. The value of ΔH_f^o for $\text{SO}_2(\text{g})$ adopted is -135 ± 10 kcal. mole⁻¹.

Heat Capacity and Entropy.

The bond distances and angles were obtained from R. C. Ferguson, J. Am. Chem. Soc. 76, 850 (1954). The vibrational frequencies were taken from R. J. Gillespie and E. A. Robinson, Can. J. Chem. 39, 2171 (1961). The assignment of these vibrational frequencies was based on the previous measurements of the infrared and Raman spectra reported by J. K. O'Loane and M. K. Wilson, J. Chem. Phys. 23, 1313 (1955), P. Bender and J. M. Wood, J. Chem. Phys. 23, 1316 (1955) and D. M. Vost, Proc. Indian Acad. Sci. B, 333 (1958). The fundamental assignment reported by J. K. O'Loane and M. K. Wilson, loc. cit., was 1333, 808, 530, (410), 748 and 390 cm.⁻¹. The three principal moments of inertia are: I_A = 1.0034 X 10⁻³⁸, I_B = 9.7421 X 10⁻³⁹ and I_C = 1.6935 X 10⁻³⁸ g. cm.².

The heat capacities of thionyl fluoride (SO_2F_2) have been measured, from 12° to 230°K., by E. L. Pace and B. P. Turnbull, J. Chem. Phys. 43, 1953 (1965), for a sample of 99.97% mole % purity. Incorporating them with the measured ΔH_f^o of 1.506 kcal. mole⁻¹ at T₀ = 143.25°K. and ΔH_f^o of 5.091 kcal. mole⁻¹ at T₀ = 228.84°K., which was derived from the measured vapor pressure of SO_2F_2 (l), the entropy of SO_2F_2 (g) at 228.84°K. was evaluated as 63.56 e.u. This value is in excellent agreement with the corresponding value, 63.522 e.u., calculated using the adopted molecular constants. This indicates the fact that the molecular constants used for the calculation of the tabulated thermodynamic functions are adequate. Hence the new vibrational frequencies suggested by Pace and Turnbull, loc. cit., were not used.

Silicon Oxide Difluoride (SiOF₂)F₂Osi

Bond Distance: Si-O = [1.60] Å Si-P = [1.54] Å $\sigma = 2$

Bond Angle: P-Si-O = [120]° P-Si-P = [120]°

Product of the Moments of Inertia: $I_A I_B I_C = 2.56608 \times 10^{-114} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

 $\Delta H_{298.15}^o$ was estimated by comparison with those for SiF₄(g) and SiO₂(g).

Heat Capacity and Entropy.

The vibrational frequencies were estimated by comparison with those for COF₂(g) and TiOF₂(g). The vibrational frequencies for COF₂(g) and TiOF₂(g) were obtained from R. J. Lovell, C. V. Stephenson, and E. A. Jones, J. Chem. Phys. 22, 1953 (1954), and J. S. Gordon, private communication, May 12, 1953, respectively. The bond distances of Si-O and Si-P were assumed to be the same as those for SiO(g) and SiF₄(g), respectively. Point group, ground state multiplicity, and bond angles were estimated.

 $\epsilon = 2$

Heat of Formation.
 ΔH_f^0 was estimated as -220 kcal. mole⁻¹ by J. S. Gordon, AstroSystems, Inc., Caldwell Twp., N. J., private communication, January 10, 1963. ΔH_f^0 298.15 was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. The principal moments of inertia are:
 $I_A = 14.3274 \times 10^{-39}$ g. cm.², $I_B = 11.6632 \times 10^{-39}$ g. cm.², and $I_C = 25.9907 \times 10^{-39}$ g. cm.²

Heat of Formation.

The heat of formation was reported by R. M. Reese, V. H. Dibeler and J. L. Franklin, J. Chem. Phys. 29, 880 (1958). The value was calculated from the appearance potential of the SO₂⁺ ion obtained from electron impact studies of SO₂ and SO₂P₂.

Heat Capacity and Entropy.

The vibrational frequencies were obtained from G. R. Hunt, and M. K. Wilson, Spectrochim. Acta, 16, 570 (1960). The bond distances and bond angles were reported by D. R. Lide, Jr., D. E. Mann, and R. M. Fristrom, J. Chem. Phys., 26, 734 (1957). The entropy of sulfuryl fluoride gas has been calculated from the calorimetric data and the third law of thermodynamics to be 62.66 cal. deg.⁻¹ mole⁻¹ at 217.78°K. by P. J. Bockhoff, R. V. Petrella, and E. L. Pace, J. Chem. Phys. 32, 799 (1960). The discrepancy between entropy value calculated from calorimetric data and that calculated from molecular and spectroscopic data (1 atm., 217.78°K) is attributed to randomness in the solid at 0°K by P. J. Bockhoff and E. L. Pace, J. Chem. Phys. 34, 3502 (1962). The vibrational frequencies reported by M. D. Perkins and M. Kent Wilson, J. Chem. Phys. 20, 1791 (1952) were 1269 (1), 846 (1), 544 (1), [500] (1), [385] (1), 1502 (1), 553 (1), 885 (1), and 539 (1) cm.⁻¹. The three principal moments of inertia are: 1.6567×10^{-38} , 1.6567×10^{-38} , and $1.6349 \times 10^{-38} \text{ g. cm.}^2$.

I_AI_BI_C = [1.9059 × 10⁻¹¹⁵] g.³ cm.⁶

σ = 2

Heat of Formation. ΔH°_f 298.15 was estimated by C. B. Henderson

and R. S. Scheffer, *Atlantic Research Corp., Alexandria, Virginia*,

"Survey of Thermochemical Data," January, 1960. For their esti-

mation they assumed certain bond energies for the dissociation of

PF₃(g). Bond one was assumed 20% greater than bond two and three

which were assumed to be equal. ΔH°_f 298.15 was corrected for the

change in phosphorus reference state (white α → red γ).

Heat Capacity and Entropy. Molecular constants and vibrational

levels were estimated by J. S. Gordon, *Thiokol Chemical Corp.,*

Reaction Motors Division, *Denville, N. J., "Thermodynamic Data*

for Combustion Products," January, 1960.

S°_{298.15} = [27.0 ± 2] gibbs/molT_m = 613°KT₁ = 725°KT_m = 1099°KΔH°_{298.15} = 58.5 kcal/mol

The heats of formation at 298.15°K derived from the enthalpy changes of different chemical reactions are listed below. The adopted one is the average of the last three ΔH°_{298.15} values, which is also in reasonable agreement with the ΔH°_{298.15} values evaluated from (1) and (5).

Heat of Formation

Reference	Chemical Reaction	ΔH° _{298.15} Kcal/mol	ΔH° _{298.15} Kcal/mol
1	PbF ₂ (c) + H ₂ (g) = Pb(l) + 2 HF(g)	32.0 ± 0.58*	-161.3 ± 0.6
2	PbF ₂ (c) + H ₂ O(g) = PbO(c) + 2 HF(g)	29.6 ± 2.1**	-154.5 ± 4.0
3	Pb(c) + F ₂ (g) = PbF ₂ (c)	-159.7 ± 0.5	-159.7 ± 0.5
4	PbO(c) + 2 HF(40% aq) = PbF ₂ (c) + H ₂ O(l)	-22.9 ± 0.3	-159.0 ± 0.5
5	PbF ₂ (c) + 2 Na(c) = Pb(c) + 2 NaF(aq)	-112.2 ± 0.2	-162.2 ± 0.4
6	PbF ₂ (c) + Mg(c) = Pb(c) + MgF ₂ (c)	-109.5 ± 1.5	-159.2 ± 2.0
7	3/2 PbF ₂ (c) + Al(c) = 3/2 Pb(c) + AlF ₃ (c)	-118.5 ± 0.1	-161.5 ± 1.0
8	3/2 PbF ₂ (c) + Al(c) = 3/2 Pb(c) + AlF ₃ (c)	-117.7 ± 0.6	-162.1 ± 1.0
9	1/2 PbF ₂ (c) + 1/3 Al(c) = 1/2 Pb(c) + 1/3 AlF ₃ (c)	-38.3 ± 0.8	-161.8 ± 1.0

* This is the third law value. The second law value is 32.4 ± 0.9 kcal/mol. The entropy drift is -0.5 ± 1.2 eu.
 ** This is the third law value. The second law value is 39.6 ± 0.7 kcal/mol. The entropy drift is -10.9 ± 0.8 eu.

Heat Capacity and Entropy

Banashek, Patsukova, and Rassonskaya (10) measured the high temperature enthalpies (H° - H°_{298.15}) for PbF₂(c) in the temperature range 670-1165°K. Based on their enthalpy measurements the heat capacity of PbF₂(c) at temperatures 725-1099°K is derived as 24.3 ± 0.2 gibbs/mol by the least square method. The heat capacities below 725°K are estimated using their reported enthalpies at 670-725°K, which are based on a mixture of β and γ, as a guide.

The S°_{298.15} is estimated to be 25 eu by the method suggested by Kubaschewski and Evans (11), and adjusted to 27 eu so that the second and third law ΔH°_{298.15} values derived from the equilibrium data reported by Jellinek and Rudat (12) are in good agreement.

Transition Data

The transition temperatures are obtained from Banashek, Patsukova, and Rassonskaya (10). The β + γ transition at 613°K was reported as either slow or irreversible and the γ + β transition at 725°K was reversible. The polymorphism of PbF₂(c) has been studied by many other investigators. However, the relations between the temperature and the character of polymorphic transformation are not consistent (10).

The enthalpy difference at 725°K for PbF₂(γ) and PbF₂(β) is ΔH°₂. The value of ΔH°₂ is estimated such that the generated functions yield reasonable agreement among the derived ΔH°₂₉₈ values (see the above table).

Melting Data

See PbF₂(l) table.

Heat of Sublimation

The difference between ΔH°_{298.15} for PbF₂(g) and PbF₂(c) is ΔH°_{298.15}.

$$S_{298.15}^{\circ} = [28.647] \text{ gibbs/mol}$$

$$\Delta H_f^{\circ} 298.15 = -158.722 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 2.98 \text{ kcal/mol}$$

$$T_m = 1099^{\circ}\text{K}$$

Heat of Formation

$\Delta H_f^{\circ} 298.15^{\circ}$ is obtained from $\Delta H_f^{\circ} 298.15^{\circ}$ (c) by adding ΔH_m° and the difference between $H_m^{\circ} - H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy

The enthalpies ($H^{\circ} - H_{298.15}^{\circ}$) of PbF₂(l) in the temperature range 1104-1165°K were determined by Banashek, Patukova, and Rassonskaya (1). Based on their reported results the heat capacity of PbF₂(l) is evaluated to be 24 ± 2 gibbs/mol by the least square method. This Cp value is adopted and extended to 298 and 2500°K, respectively.

The entropy ($S_{298.15}^{\circ}$) is calculated in a manner analogous to that of the heat of formation.

Melting Data

T_m is taken from Banashek, Patukova, and Rassonskaya (1). The enthalpy difference at T_m for PbF₂(l) and PbF₂(s) is ΔH_m° .

Other values of T_m (°K) reported are 1091 (2, 11), 1097 (3, 4, 5) and 1128 (6). Using the freezing point data of binary systems PbF₂-PbBr₂ (5), PbF₂-PbCl₂ (5, 7), PbF₂-PbI₂ (5, 8), PbF₂-PbO (9), and PbF₂-NaF (10), Kelley (3) evaluated the corresponding values of ΔH_m° (kcal/mol) as 1.70, 1.70, 1.96, 3.87, and 2.47. Other reported values of ΔH_m° are 3.00 (1) and 4.16 (2) kcal/mol.

Vaporization Data

From mass spectroscopic study on the vapor species in PbF₂, Zmbov, Hastie, and Margrave (4) have shown that molten PbF₂ vaporizes partly as molecular PbF₂. There is considerable disproportionation, and at 715°C the vapor composition is approximately 68% PbF₂, 25% PbF, 21% PbF, and 74% Pb (4, 12). T_b has been reported as 1565°K (11) where the vapor is expected to be a mixture of the above species.

Heat of Formation

Vapor pressure data for PbF₂ have previously been interpreted on the assumption that PbF₂ was the only species present in the gas phase (1, 2). Zmbov, Hastie, and Margrave (3) have studied the vapor species over PbF₂(c, l) mass spectrometrically and shown that PbF₂ vaporizes only partly as molecular PbF₂ and there is considerable disproportionation. The vapor composition at 988°K is approximately 66% PbF₄, 25% PbF₂, 2% PbF, and 7% Pb (3, 4). From extrapolation of the ion intensity data from 1043 to 988°K to the temperature region in which Mesnayanov and Iofa (2) measured the saturated vapor pressures of PbF₂(c), 792-988°K, by Knudsen effusion method, the partial pressure of PbF₂(c), at 988°K was calculated to be 0.0435 ± 0.005 torr. Based on this calculated vapor pressure, the heat of sublimation (ΔH_{298}°) of PbF₂(c) is derived as 88.50 kcal/mol by the third law method, yielding ΔH_f° (PbF₂, g) = -103.3 ± 1 kcal/mol.

Due to lack of data on vapor compositions over PbF₂(c, l) at various temperatures, the partial pressure measurements reported by Wartenberg and Boses (1), using boiling point method, and those of Mesnayanov and Iofa (2) are not used for evaluation.

Heat Capacity and Entropy

The bond distance was determined by Akishin, Spiridonov and Khodchenkov (5). The bond angle is assumed to be the same as that in PbF₂(g) where X = Cl, Br or I (6). The vibrational frequencies are calculated by valence force method (10) using force constants estimated by comparison with those for PbF (7), CaF₂ (8), HgF₂ (9), and MgF₂ (9). The value of ν_2 is in fair agreement with the value, 145 cm^{-1} , estimated by (9). The three principal moments of inertia are: $I_A = 1.5559 \times 10^{-38}$, $I_B = 1.1040 \times 10^{-38}$, and $I_C = 2.6599 \times 10^{-38} \text{ g cm}^2$.

Heat of Formation

J. L. Margrave, A. S. Kanaan, and D. C. Pease, J. Phys. Chem. **66**, 1200 (1962), have reported some approximate equilibrium constants for the reaction $\text{Si}(g) + \text{SiF}_4(g) \rightleftharpoons 2\text{SiF}_2(g)$. These were calculated from yields of polymerized products and a knowledge of the total system pressure given in U. S. Patent No. 2,840,588 (1958). The data were subjected to third law analysis using the present JANAF functions and yielded $\Delta H_{298}^\circ = 92 \pm 10$ kcal/mol, which gives $\Delta H_f^\circ(\text{SiF}_2, g) = -147 \pm 5$ kcal/mol.T. C. Ehlert and J. L. Margrave, J. Chem. Phys. **41**, 1056 (1964), have reported equilibrium constants for three reactions determined mass spectrometrically.A. $\text{CaF}_2(c) + \text{Si}(g) + \text{Ca}(g) + \text{SiF}_2(g)$ B. $\text{CaF}_2(g) + \text{Si}(g) + \text{Ca}(g) + \text{SiF}_2(g)$ C. $2\text{CaF}(g) + \text{Si}(g) + 2\text{Ca}(g) + \text{SiF}_2(g)$

A 2nd and 3rd law analysis of the data is shown below.

We adopt $\Delta H_{298.15}^\circ(\text{SiF}_2, g) = -140.5 \pm 3$ kcal/mol.

Heat Capacity and Entropy

The microwave, ultraviolet and infrared spectra have all been extensively studied (1, 2, 3, 4, 5, 6, 7). We have adopted the vibrational frequencies and molecular structure from V. M. Khanna et al. (1). The electronic levels are from V. M. Khanna et al. (2) with an estimated triplet level by analogy with CF_2 .The individual moments of inertia are $I_A = 2.7482 \times 10^{-39}$ g cm², $I_B = 9.5100 \times 10^{-39}$ g cm², and $I_C = 12.2582 \times 10^{-39}$ g cm².

Heat of Formation
Zabov and Margrave (1) have reported ion intensities and the corresponding equilibrium constants for the reaction
 $\text{Ca(g)} + \text{TiF}_3(\text{g}) = \text{CaF(g)} + \text{TiF}_2(\text{g})$. Second and third law analyses of their data give a second law ΔH_{298}° of 7.0 kcal/mol, a third law ΔH_{298}° of 11.76 kcal/mol and a third law drift of 3.1 ± 3.8 eu. The heat of formation, ΔH_{298}° , of $\text{TiF}_2(\text{g})$ is calculated from the third law ΔH_{298}° , above, and the JANAF heat of formation of $\text{TiF}_3(\text{g})$, CaF(g) and Ca(g) .

Heat Capacity and Entropy

The interatomic distances are estimated from those of TiCl_2 , TiCl_4 , and TiF_4 . The vibrational frequencies are estimated from a valence force field model.

The electronic levels are assumed to be the same as $\text{TiCl}_2(\text{g})$. The levels of $\text{TiCl}_2(\text{g})$ are estimated by assuming they correspond to the inverted states of $\text{NiCl}_2(\text{g})$ (2). The linear configuration is assumed because experimental evidence (3) indicates that other transition metal difluorides, viz. those of Mn, Co, Ni, Cu, and Zn, are linear.

(CRYSTAL)

ZIRCONIUM DIFLUORIDE (ZrF₂)Zirconium Difluoride (ZrF₂)

(Crystal) GFW = 129.2168

 $\Delta H_f^\circ = \text{Unknown}$ $\Delta H_f^\circ_{298.15} = [-230 \pm 15] \text{ kcal/mol}$ $\Delta H_m^\circ = [9 \pm 2] \text{ kcal/mol}$ $\Delta H_s^\circ_{298.15} = [96.6] \text{ kcal/mol}$ $S^\circ_{298.15} = [18 \pm 2] \text{ gibbs/mol}$ $T_m = [1175 \pm 150]^\circ \text{K}$

Heat of Formation

More recent thermal data related to the heat of formation of ZrF₂(c) is unavailable. The adopted $\Delta H_f^\circ_{298}(\text{ZrF}_2, \text{c})$ value is taken from (1) which was estimated by Brewer (2).

Heat Capacity and Entropy

The heat capacities in the temperature range 298-2000°K are estimated by comparison with those of ZrF₄(c) and Zr(c). The S°_{298} is calculated as 17.2 and 17.0 eu based on the assumptions that $S(\text{ZrF}_2) = 1/2[S(\text{ZrF}_4) + S(\text{Zr})]$ and $S(\text{ZrF}_2) = S(\text{ZrF}_2) - S(\text{Zr}) + S(\text{Zr})$. Using the additive entropy constants $S^\circ_{298} = 12.1$ and 4.7 eu for Zr and F suggested by Kubaschewski and Evans (3), we obtain $S^\circ_{298}(\text{ZrF}_2, \text{c}) = 12.1 + 2(4.7) = 21.5$ eu. Based on $S^\circ_{298} = 11.5$ and 3.9 eu for Zr* and F* recommended by Kelley (4), the value $S^\circ_{298}(\text{ZrF}_2, \text{c})$ is derived as 19.3 eu. The entropy at 298°K for ZrF₂(c) is tentatively adopted as 18 ± 2 eu.

Melting Data

Both T_m and ΔH_m° are estimated. The derived entropy of melting, 2.55 eu/atom, is the same as that of ZrF₄(c) which was obtained from experimental measurements (5). Therefore these estimated values are tentatively adopted.

Heat of Sublimation

The difference between $\Delta H_f^\circ_{298}$ for ZrF₂(g) and ZrF₂(c) is $\Delta H_s^\circ_{298}$.

$$S_{298.15}^{\circ} = [24.103] \text{ gibbs/mol}$$

$$\Delta H_f^{\circ}{}_{298.15} = [-222.502] \text{ kcal/mol}$$

$$T_m = [1175 \pm 150]^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = [9 \pm 2] \text{ kcal/mol}$$

$$T_b = [2529]^{\circ}\text{K}$$

$$\Delta H_v^{\circ} = [69.0] \text{ kcal/mol}$$

Heat of Formation

The $\Delta H_f^{\circ}{}_{298}(l)$ is obtained from $\Delta H_f^{\circ}{}_{298}(c)$ by adding ΔH_m° and the difference between H_{1175}° - H_{298}° for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is estimated from those of $ZrF_4(l)$, $CaF_2(l)$, and $Ca(l)$, and is assumed to be constant in the temperature range 800-3000°K. A glass transition temperature is assumed at 800°K. The Cp values below 800°K are adopted from the $ZrF_2(c)$ table.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

Both T_m and ΔH_m° are estimated. The derived entropy of melting, 2.55 eu/atom, is the same as that of $ZrF_4(c)$ which was obtained from experimental measurements (1). Therefore these estimated values are tentatively adopted.

Vaporization Data

T_b is the temperature at which the Gibbs energy change of the process $ZrF_2(l) = ZrF_2(g)$ approaches zero. The difference between ΔH_f° for $ZrF_2(l)$ and $ZrF_2(g)$ at T_b is ΔH_v° .

ΔH_f^o = UnknownΔH_f^o 298.15 = -249 ± 3 kcal. mole⁻¹ΔH_f^o 298.15 = [52.6] kcal. mole⁻¹S_{298.15}^o = [23.5 ± 2] cal. deg.⁻¹ mole⁻¹T_g = [1200]*K.

Heat of Formation.

The equilibrium pressures for the reaction $2\text{FeF}_3(\text{c}) + \text{H}_2(\text{g}) = 2\text{Fe}(\text{g}) + 2\text{HF}(\text{g})$ have been measured at temperatures 623, 723 and 823°K. by K. Jellinek and A. Rudat, Z. anorg. allgem. Chem. 175, 281 (1928). Using the reported data, the enthalpy change of the reaction was evaluated as 37.9 and 31.3 kcal. mole⁻¹ by the third and second law methods, respectively. The corresponding ΔH_f° 298.15 (FeF₃, c) values are calculated to be -252.4 and -249.2 kcal. mole⁻¹. The equilibrium constants for the reaction $2\text{FeF}_3(\text{c}) + 3\text{H}_2\text{O}(\text{g}) = \text{Fe}_2\text{O}_3(\text{c}) + 6\text{HF}(\text{g})$ were determined by L. Donange, Ann. Chim., 7, 225 (1937). Based on the third law value of ΔH_f° 298.15° 62.0 kcal. mole⁻¹, the ΔH_f° 298.15 (FeF₃, c) was calculated as -237.4 kcal. mole⁻¹. The value of ΔH_f° 298.15 for FeF₃(c) is selected to be -249 ± 3 kcal. mole⁻¹.

Heat Capacity and Entropy.

The heat capacities of FeF₃(c) at temperatures 100-450°K. were determined by H. Bizette, R. Mainard and J. Picard, Comp. rend. 5508 (1965). The results were presented graphically by plotting C_p vs. T. The C_p curve shows a peak at 367°K. An antiferromagnetic transition at about 394°K. was reported by E. O. Wollan, H. R. Child, W. C. Koshler and M. K. Wilkinson, Phys. Rev. 112, 1132 (1958). The heat capacities above 450°K. and 6298.15 were estimated by comparison with those for FeCl₃(c) AlCl₃(c) and AlF₃(c).

Sublimation Data.

The phenomenon that FeF₃(c) sublimes without fusion at temperatures near 1000°C has been observed and reported by Poulenc, Ann. Chim. phys. (7), 2, 1 (1894). Based on this data the value of T_m was estimated. The value of heat of sublimation (ΔH_s° 298.15) was calculated using an estimated entropy of sublimation, $\Delta S_s^\circ = 40$ e.u. in order to have $\Delta H_s^\circ = 0$ for the reaction $\text{FeF}_3(\text{c}) = \text{FeF}_3(\text{g})$ at 1200°K.

Iron Trifluoride (FeF₃)

(Ideal Gas) Mol. Wt. = 112.8422

[600] (1) [800] (2)
 [250] (1) [220] (2)

Bond Distance: Fe-F = [1.9] cm.⁻¹
 Bond Angle: F-Fe-F = [120]°
 Product of the Moments of Inertia: $I_A I_B I_C = [9.96723 \times 10^{-114}] \text{ g.}^3 \text{ cm.}^6$
 $\sigma^\circ = [6]$

Heat of Formation.

The value of $\Delta H_f^\circ 298.15$ (FeF₃, g) was calculated from $\Delta H_f^\circ 298.15$ and $\Delta H_f^\circ 298.15$ for FeF₃(c). The value $\Delta H_f^\circ 298.15 = 65.5 \text{ kcal. mole}^{-1}$ was derived from $\Delta H_f^\circ 1200$ (see FeF₃(c) table for details).

Heat Capacity and Entropy.

The molecular structure, bond distance and angle were estimated by comparison with those for AlF₃(g). The vibrational frequencies were estimated by comparison with those for AlF₃(g), TiF₃(g) and ZrF₃(g). The three principal moments of inertia are: $I_A = I_B = 1.7081 \times 10^{-38} \text{ g. cm.}^2$ and $I_C = 3.4162 \times 10^{-38} \text{ g. cm.}^2$.

Heat of Formation. ΔH_f^o 298.15 was found estimated in C. B. Henderson and R. S. Scheffer, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

Heat Capacity and Entropy. Vibrational levels and multiplicities were assigned by C. Newman, S. Polo and M. Wilson, Spec. Chim. Acta 15, 793 (1959). Constants used in calculating moment of inertia came from G. Heath, L. Thomas, and J. Sheridan, Trans. Far. Soc. 50, 779 (1954).

Lithium Fluoride, Trimeric (Li_3F_3)

(Ideal Gas) $\text{GFW} = 77.8122$

LITHIUM FLUORIDE, TRIMERIC (Li₃F₃)

(IDEAL GAS)

GFW = 77.8122

Point Group $[D_{2h}]$
$$\Delta H_f^\circ = -361.02 \pm 6.0 \text{ kcal/mol}$$
 $\Delta G_{298}^{\circ} = [76 \pm 2] \text{ kJ/mol}$
$$\Delta H_{f, 298.15}^{\circ} = -362.62 \pm 6.0 \text{ kcal/mol}$$

Ground State Quantum Weight = [1]

weight = [1]
Vibrational Frequencies and Degeneracies

Bond Distance: Li-F = [1.68] Å

Bond Angles: $F-Li-F = 120^\circ$ $Li-F-Li = 120^\circ$

Product of the Moments of Inertia: $I_{YY} = [1.2122 \times 10^{-11}] \text{ cm}^6$

Heat of Formation

The heat of formation (ΔH_f°) is based on the adopted value $\Delta H_{298}^\circ = 79.73$ kcal/mol for the reaction $3\text{LiF}(c) = \text{Li}_3\text{F}_3(g)$, using $\Delta H_f^\circ(\text{LiF}, c) = -147.45$ kcal/mol. The ΔH_{298}° value is calculated to be 73.9 kcal/mol at 1000°K, which is in good agreement with the values $\Delta H_{1000}^\circ = 73.9 \pm 3$ and 74.9 ± 1 kcal/mol reported by Buchler and Stauffer (3) and Aikshin et al. (2), respectively. Using the adopted ΔH_{298}° values for monomer, dimer, and trimer, we also evaluate the value $\Delta H_{298}^\circ(\text{Li}_3\text{F}_3, g) = 53.8$ kcal/mol for the reaction $\text{Li}_3\text{F}_3(g) = \text{Li}_2\text{F}_2(g) + \text{LiF}(g)$ which is in agreement with the value 50 ± 4 kcal/mol reported by Porter and Schoonmaker (3). Rothberg et al. (4) have determined the partial pressures of LiF monomer, dimer, and trimer in the temperature range 980–1070°K, using the molecular-beam velocity-selector method (5). However, the total pressures derived from these data are too low in comparison with the other reported vapor pressures. Thus our data are not adopted for evaluation.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of the BeO trimer. The Li-F bond distance is taken from that of the Li_2F_2 molecule determined by Akishin and Rambidi (6). Four vibrational frequencies, ν_1 and three ν_2 , are reported by Shelnov (7) from analysis of the infrared spectra of LiF using the matrix isolation technique. The reported frequencies are corrected to the average isotopic species. The other four frequencies, ν_3 and three ν_4 , are estimated by comparison with those for the isoelectronic molecule Be_3O_3 . The three principal moments of inertia are $I_A = I_B = 0.923 \times 10^{-38}$ and $I_C = 3.646 \times 10^{-38}$ g cm².

Vibrational Frequencies and Degeneracies

 $\frac{\omega_e}{\text{cm}^{-1}}$

1032 (1)

642 (1)

906 (2)

492 (2)

 $\sigma = 3$

Bond Distance: N-F = 1.371 Å

Bond Angle: F-N-F = 102.9°

Product of the Moments of Inertia: $I_A I_B I_C = 8.855 \times 10^{-115} \text{ g}^3 \text{ cm}^6$

Heat of Formation

The adopted heat of formation was obtained from a simultaneous adjustment of several interrelated pieces of data relating to the heat of formation of HF (see HF, g table 12-31-68). The data which was considered relating directly to NF₃ was as follows.

A. $8 \text{ NF}_3(\text{g}) + 3 \text{ C}_2\text{H}_4(\text{g}) \rightarrow 6 \text{ CF}_4(\text{g}) + 7 \text{ N}_2(\text{g})$ Walker (1) reported $\Delta H_r^\circ = -1308.8 \pm 1.3 \text{ kcal/mol}$.B. $\text{NF}_3(\text{g}) + 1.5 \text{ H}_2(\text{g}) \rightarrow \text{NH}_3(\text{g}) + 0.5 \text{ N}_2(\text{g})$ Sinko (2) reported $\Delta H_r^\circ = -199.49 \pm 0.22 \text{ kcal/mol}$ for a final state of HF(123 H₂O); the corrected value is $-199.40 \pm 0.22 \text{ kcal/mol}$.C. $2 \text{ NF}_3(\text{g}) + \text{S}(\text{c, rh}) \rightarrow \text{SF}_6(\text{g}) + \text{N}_2(\text{g})$ Walker (3) reported $\Delta H_r^\circ = -228.26 \pm 0.25 \text{ kcal/mol}$.D. $\text{NF}_3(\text{g}) \rightarrow 0.5 \text{ N}_2(\text{g}) + 1.5 \text{ F}_2(\text{g})$ Sinko (4) reported $\Delta H_r^\circ = 31.44 \pm 0.3 \text{ kcal/mol}$ for the above dissociation from experimental explosion of hydrogen in 10 percent and 100 percent excess NF₃.E. $\text{NF}_3(\text{g}) + \text{H}(\text{c, p}) \rightarrow \text{BF}_3(\text{g}) + 0.5 \text{ N}_2(\text{g})$ Ludwig and Cooper (5) reported $\Delta H_r^\circ = -239.46 \pm 1.2 \text{ kcal/mol}$, 5 percent of the boron remained unreacted and was detected by analysis.

Further details of the simultaneous adjustment are given by Syverud (6).

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Schatz and Levin (7) and are in good agreement with those of Pace and Pierce (8), and Wilson and Polo (9). The adopted values are also in agreement with the Raman studies of Kotov and Tatevskii (10). The bond length and angle were from the microwave studies of Sheridan and Gordy (11), whose values are in substantial agreement with the electron diffraction results of Schomaker and Lu (12).

The individual moments of inertia are $I_A = I_B = 7.854 \times 10^{-39} \text{ g cm}^2$ and $I_C = 14.354 \times 10^{-39} \text{ g cm}^2$.

Pierce and Pace (13) have obtained the entropy of the gas at 144.15°K from solid heat capacity measurements and the heats of melting and vaporization. Their reported value of 54.50 eu is in good agreement with our calculated value of 54.56 eu.

Vibrational Frequencies and Degeneracies

ω, cm⁻¹ω, cm⁻¹

Bond Distance: N-O = [1.15] Å N-F = 1.48 ± 0.1 Å

Bond Angle: ONF = [109° 28'] ONF = [109° 28']

Product of the Moments of Inertia: I_AI_BI_C = [4.0703 × 10⁻¹¹⁴] g³ cm⁶

Heat of Formation

Bougon et al. (1) determined equilibrium constants for the reaction NOF(g) + F₂(g) ⇌ NOF₃(g) as a function of temperature and total pressure. Second and third law analyses of these equilibrium data are given below:

Set I	Set II	No. of Points	Temp. Range, °K	ΔH _f ° ₂₉₈ , kcal/mol	Drift
7	1	7	533-643	-17.1	-18.7
		1	533.2	-18.2	-2.442.1

Set I contains their equilibrium data as a function of temperature, while Set II is their adopted equilibrium constant, K_p(533.2°K) = 0.015 ± 0.005 atm.⁻¹, corresponding to the lowest pressure (103 atm.) that was studied. Estimated corrections for nonideality are small and neglected. Adopting ΔH_f°₂₉₈ = -18.7 ± 1.0 kcal/mol, we derive ΔH_f°(NOF₃, g) = -34.4 ± 1.4 kcal/mol with ΔH_f°(NOF, g) = -15.7 ± 0.4 kcal/mol (2).

Armstrong and King (3) determined ΔH_f°₃₀₀ = -253.7 ± 0.6 kcal/mol for the reaction NOF₃(g) + 5/2 H₂(g) + 122 H₂O(l) + 1/2 N₂(g) + [3HF·123 H₂O(l)] in a constant pressure flame calorimeter. Combining this result with their earlier enthalpy data for reduction reactions involving F₂(g) and O₂(g) with H₂(g), they obtained ΔH_f°₃₀₄(NOF₃, g) = -44.7 ± 1.5 kcal/mol. Very recently, Dibeir and Walker (4) investigated the photolysis of NOF₃ by mass spectrometry. From their ionization threshold data, they determined ΔH_f°₀(NOF₃, g) = -69.6 ± 1.2 kcal/mol.

The value for the heat of formation of gaseous NOF₃ is tentatively selected as -39.0 ± 5.0 kcal/mol.

Heat Capacity and Entropy

Several recent infrared (5, 6, and 7) and Raman (8) studies of NOF₃ have been reported in the literature. The fundamental vibrational frequencies observed in the infrared spectrum of the molecule by the various investigators are in good agreement, although the assignment of the ν₃ and ν₅ bending modes has varied. Fox et al. (6) assigned ν₃ = 558 cm⁻¹ and ν₅ = 528 cm⁻¹, while Curtis et al. (7) reversed the assignments. Very recently, Abramowitz and Levin (8) investigated the Raman spectrum of polycrystalline film of NOF₃ at 78°K and assigned ν₃ = 535 cm⁻¹ and ν₅ = 522 cm⁻¹, consistent with the infrared work of Fox et al. (6). The fundamental vibrational frequencies and assignments given by Fox et al. (6) are adopted here.

Fox et al. (6) also investigated the nuclear magnetic resonance spectrum of NOF₃ which indicated that the molecule contained three equivalent fluorine atoms. This result, along with the general appearance of the infrared spectrum, clearly establishes that the molecule has C_{3v} symmetry. The N-O bond distance and bond angles are estimated quantities from the work of Curtis et al. (7). These estimated data have been used in calculating the N-F bond distance from the rotational constants given by Curtis et al. (7). Individual moments of inertia calculated from the structural data given above are: I_A = I_B = 14.86 × 10⁻³⁹ g cm², and I_C = 18.44 × 10⁻³⁹ g cm².

Bond Angle: F-P-F = 102.5° ± 2° F-P-O = 115.8° ± 2°

Product of Moments of Inertia: I_AI_BI_C = 5.9019 × 10⁻¹¹⁴ g³ cm⁶

Heat of Formation

Ebel and Bretcher (1) measured the enthalpy change for the following reaction:

They reported a heat of reaction of -70.6 ± 1 kcal/mol. Combining this result with the heat of formation of PF₃, ΔHf°₂₉₈ = -224.9 ± 0.9 kcal/mol (2), we derive, ΔHf°₂₉₈(POF₃, g) = -295.6 ± 1.9 kcal/mol.

Heat Capacity and Entropy

The vibrational frequencies are from the infrared studies of Selig and Claassen (3) and are in good agreement with the Raman and infrared studies of Gutowsky and Liehr (4). Several microwave studies (5, 6, 7) of POF₃ have been reported. As pointed out by Williams et al. (7), the rotational constant calculated from their microwave studies leads to a moment of inertia, I_B, which is in disagreement with the moment of inertia calculated from the molecular constants obtained from electron-diffraction studies by Brockway and Beach (8). Since insufficient microwave data were available for an independent determination, Williams et al. (7) sought to find parameters which were consistent with both measurements. Their molecular constants are adopted for this tabulation. Individual moments of inertia are I_A = I_B = 18.244 × 10⁻³⁹ g cm² and I_C = 17.731 × 10⁻³⁹ g cm².

Dec. 31, 1960; June 30, 1962; Dec. 31, 1963; Dec. 31, 1969

Vibrational Frequencies and Degeneracies

ω, cm^{-1}	ω, cm^{-1}
892 (1)	860 (2)
487 (1)	344 (2)

Bond Distance: P-F = $1.5700 \pm 0.0012 \text{ \AA}$ P...F = $2.3643 \pm 0.0028 \text{ \AA}$ Bond Angle: F-P-F = $97.8 \pm 0.2^\circ$ Product of Moments of Inertia: $2.0621 \times 10^{-114} \text{ g}^3 \text{ cm}^6$ $\sigma = 3$

Heat of Formation

Berthelot (1) measured the heats of hydrolysis of PF₃(g) and PCl₃(l). These results can be combined to give, $\Delta H_f^\circ =$ 24.5 kcal/mol , for the reaction $\text{PF}_3(\text{g}) + 3\text{HCl} \cdot 157 \text{ H}_2\text{O} + \text{PCl}_3(\text{l}) + 3\text{H}_2\text{O} \cdot 112 \text{ H}_2\text{O}$

Combining this result with the following heat of formation data,

 $\Delta H_f^\circ(\text{PCl}_3, \text{l}) = -72.2 \text{ kcal/mol}$ (2) $\Delta H_f^\circ(\text{PCl}_3, \text{g}) = -100.0 \text{ kcal/mol}$ (3) $\Delta H_f^\circ(\text{HCl} \cdot 157 \text{ H}_2\text{O}) = -138.5 \text{ kcal/mol}$ (3) $\Delta H_f^\circ(\text{H}_2\text{O} \cdot 112 \text{ H}_2\text{O}) = -138.5 \text{ kcal/mol}$ (3)we derive, $\Delta H_f^\circ(\text{PF}_3, \text{g}) = -212.2 \text{ kcal/mol}$.Dunn and Mykytyk (4) reported a heat of reaction of -2.361 kcal/mol (corrected to 25°C) for the following reaction $\text{PCl}_3(\text{g}) + 3/2 \text{ CaF}_2(\text{s}) + \text{PF}_3(\text{g}) + 3/2 \text{ CaCl}_2(\text{s})$

Combining this result with the following heat of formation data,

 $\Delta H_f^\circ(\text{PCl}_3, \text{g}) = -84.4 \text{ kcal/mol}$ (2) $\Delta H_f^\circ(\text{CaF}_2, \text{s}) = -212.9 \text{ kcal/mol}$ (3) $\Delta H_f^\circ(\text{CaCl}_2, \text{s}) = -190.0 \text{ kcal/mol}$ (3)we derive, $\Delta H_f^\circ(\text{PF}_3, \text{g}) = -224.9 \pm 0.9 \text{ kcal/mol}$.Recently, Rudzitis et al. (5) measured the heat of combustion of PF₃ in fluorine in a two-chambered bomb calorimeterat 25°C . They reported a heat of combustion of $-152.0 \pm 0.2 \text{ kcal/mol}$ for the reaction $\text{PF}_3(\text{g}) + \text{F}_2(\text{g}) \rightarrow \text{PF}_5(\text{g})$ Combining this result with the heat of formation of PF₅, $\Delta H_f^\circ(\text{PF}_5, \text{g}) = -376.9 \pm 0.7 \text{ kcal/mol}$ (7), we derive, $\Delta H_f^\circ(\text{PF}_3, \text{g}) = -224.9 \pm 0.9 \text{ kcal/mol}$. This result is adopted for this tabulation.

Heat Capacity and Entropy

The vibrational frequencies are those reported by Wilson and Palo (8). Several different values for the P-F bond

length and F-P-F bond angle have been reported in the literature. This problem was recently discussed by Morino et al.

(9), who also reported new data obtained from electron-diffraction studies. Their results are adopted for this tabulation.

Individual moments of inertia calculated according to their structure are: $I_A = I_B = 10.814 \times 10^{-39} \text{ g cm}^2$ and $I_C =$ $17.634 \times 10^{-39} \text{ g cm}^2$.

Bond Distance: Si-F = (1.56) Å

Bond Angle: F-Si-F = (109.47)°

Product of the Moments of Inertia: I_AI_BI_C = 2.5135 × 10⁻¹¹⁴ g³ cm⁶

σ = 3

Heat of Formation

The heat of formation is estimated from the assumption of a 0.5 kcal heat for the reaction:

ΔH_{f,298}^o(SiF₃, g) = -263 kcal/mol is derived from ΔH_{f,298}^o(SiF₄, g) = -385.98 kcal/mol and ΔH_{f,298}^o(SiF₂, g) = -140.5 kcal/mol. The above value is confirmed by the observations of Layne (1), whose total pressure data above the silicon-fluoride system agree with those calculated from these tables.

Heat Capacity and Entropy

The bond length is estimated between those of SiF₄ and SiF₂. The vibrational frequencies are from Milligan et al. (2), and the angle is taken to be tetrahedral, since they also reported an angle of approximately 71° between the Si-F bonds and the threefold axis. The spectra of the radical were obtained in inert gas matrices and all the fundamentals were observed. The individual moments of inertia are I_A = I_C = 11.081 × 10⁻³⁹ g cm², I_B = 20.472 × 10⁻³⁹ g cm².

Heat of Formation

Blocher and Hall (1) have reported vapor pressure data for the process $1/2\text{Hg}_2\text{F}_2 + \text{TiF}_3(\text{c}) = \text{TiF}_4(\text{g}) + \text{Hg}(\text{l})$. Second and third law analyses of their data give a second law ΔH_{298} of 23.7 kcal/mol, a third law ΔH_{298} of 29.86 kcal/mol, and a third law drift of 11.9 ± 1.0 eu. The third law value is combined with the JANAF values for the heat of formation of $\text{Hg}_2\text{F}_2(\text{c})$ and $\text{TiF}_4(\text{g})$ to give a ΔH_{298} of -343.1 ± 10.0 kcal/mol. The large uncertainty on ΔH_{298} is assigned because Blocher and Hall were not able to identify $\text{TiF}_3(\text{c})$ as the reaction product in the above process. They reported that the X-ray pattern of the products contained lines corresponding to $\text{Hg}_2\text{F}_2(\text{c})$ plus others that did not correspond to $\text{TiF}_3(\text{c})$.

Heat Capacity and Entropy

The heat capacity of $\text{TiF}_3(\text{c})$ is estimated from the heat capacities of ZrF_4 and TiF_4 . The entropy, S_{298} , is estimated from CrF_3 and from ionic entropy contributions. Both methods give values which are within ±0.8 eu of the chosen value of 21 ± 3 eu.

Heat of Sublimation

The heat of sublimation is calculated from the vapor pressure data of Zmbov and Margrave (2). See $\text{TiF}_3(\text{g})$ table for details. The sublimation temperature is taken as the point at which $\Delta G = 0$ for the reaction $\text{TiF}_3(\text{c}) = \text{TiF}_3(\text{g})$.

Heat of Formation

The heat of formation of TiF₃(g) is calculated from that of TiF₃(c) and the heat of sublimation determined from the mass spectrometric vapor pressure data of Zmbov and Margrave (1). Their data give nine points over the temperature range 759 - 865°K.

Second and third law analyses of their data give a second law ΔHf°₂₉₈ of 61.2 ± 0.4 kcal/mol and a third law ΔHf°₂₉₈ of 59.0 kcal/mol with an entropy drift of -2.7 ± 0.5 units. The third law value is used to calculate ΔHf°₂₉₈.

Heat Capacity and Entropy

The internuclear distance is estimated from those of TiF₄(g), and TiCl₃(g), and TiCl₄(g). The pyramidal bond angle is estimated assuming TiF₃(g) similar to the group V trihalides. The principal moments of inertia are I_A = 1.68 × 10⁻³⁸ g cm² and I_C = 2.66 × 10⁻³⁸ g cm². The vibrational frequencies are estimated from those of PF₃ and AsF₃. The electronic levels are estimated from the levels of Ti³⁺ (2).

F₃Ti

Zirconium Trifluoride (ZrF₃)

GFW = 148.2152

$$S_{298.15}^{\circ} = \{21 \pm 2\} \text{ gibbs/mol}$$

$$\Delta H_f^{\circ} = \text{Unknown}$$

$$\Delta H_f^{\circ} = [-335 \pm 20] \text{ kcal/mol}$$

$$\Delta H_{298.15}^{\circ} = [70.1] \text{ kcal/mol}$$

Heat of Formation

The heat of formation at 298°K for ZrF₃(c) was reported as -350 kcal/mol (1) which was estimated by Brewer (2). Based on this ΔH_{298}° value, the crystal lattice energy (U) of ZrF₃(c) is calculated to be 1371 kcal/mol by the Born-Haber cycle method (3). For the evaluation of U from the relation: $\Delta H_f^{\circ}(\text{ZrF}_3, c) = \Sigma I_i + L - 3(E - D/2) - U$, the following values (kcal/mol) are used: ΣI_i (the sum of the successive three ionization potentials of Zr metal) = 1055 (4), L (the enthalpy of sublimation of Zr metal) = 148.3 (5), E (the electron affinity of fluorine) = 79.5 (6), and D (the enthalpy of dissociation of fluorine) = 37.7 (2). The derived value of U(ZrF₃, c) is of the same order of magnitude of the value, U(TiF₃, c) = 1376 kcal/mol, calculated by Cavell and Clark (3) using the same method.

From $\Delta H_{298}^{\circ}(\text{ZrF}_3, c) = -350$ kcal/mol, the derived $\Delta G_f^{\circ}(\text{ZrF}_3, c)$ values indicate that ZrF₃(c) is thermodynamically more stable than the system ZrF₄(c) + Zr(c). For example, in the temperature range 798-1200°K, the Gibbs energy changes for the reaction $3 \text{ ZrF}_3(c) + \text{Zr}(c) = 4 \text{ ZrF}_4(c)$ are about -29 ± 1 kcal/mol. However, this product ZrF₃(c) has never been prepared successfully from this reaction in many laboratories (8). In order to make the $\Delta G_f^{\circ}(\text{ZrF}_3, c)$ values consistent with the experimental observations, the heat of formation of ZrF₃(c) is arbitrarily adjusted to be 15 kcal/mol less negative, or $\Delta H_{298}^{\circ}(\text{ZrF}_3, c) = -335$ kcal/mol with uncertainty as high as ±20 kcal/mol. This value is tentatively adopted.

The Gibbs energy changes for the reaction $3 \text{ ZrF}_3(g) + \text{Zr}(c) = 4 \text{ ZrF}_4(c)$ are evaluated to be very favorable at temperatures below 900°K, e.g., $\Delta G_r^{\circ} = -93.9$ and -6.7 kcal/mol at 298 and 900°K, respectively. But according to Larsen and Leddy (9), this reaction does not occur in the temperature range 473-973°K, and pressure range 5-15 atm. One possible explanation is that these heterogeneous reactants may require very high activation energy to initiate the reaction. In other words, this reaction is unfavorable at these temperatures probably due to kinetic rather than thermodynamic reasons.

Heat Capacity and Entropy

The heat capacities of ZrF₃(c) are not available in the literature. They are estimated from the Cp values of ZrF₄(c) by deduction of one F atom Cp contributions which are calculated as $1/4(Cp_{\text{ZrF}_4(c)} - Cp_{\text{Zr}(c)})$. The $S_{298.15}^{\circ}$ is taken to be $1/2(S_{298}^{\circ}(\text{ZrF}_4, c) + S_{298}^{\circ}(\text{ZrF}_2, c))$ of which the value $S_{298}^{\circ}(\text{ZrF}_2, c)$ is estimated (see ZrF₂(c) table for details).

Heat of Sublimation

The difference between ΔH_{298}° for ZrF₃(g) and ZrF₃(c) is ΔH_{298}° . Actually, ZrF₃(c) is thermodynamically unstable, e.g., the Gibbs energy changes for the reaction $4 \text{ ZrF}_3(c) = 3 \text{ ZrF}_4(c) + \text{Zr}(c)$ are about -30 kcal/mol in the temperature range 298-1400°K. In other words, ZrF₃(c) decomposes into ZrF₄(c) + Zr(c) before sublimation occurs.

Heat of Formation

Murad and Hildenbrand (1) studied the gaseous equilibria involving ZrF₄, ZrF₃, ZrF₂, Ca and CaF₂. These species were generated at high temperatures in a graphite Knudsen cell containing powdered calcium fluoride and elemental zirconium. Ion intensities were measured 3 eV above threshold over the temperature range 1665-1747°K and the equilibrium constants were calculated for the following isomolecular reaction: Ca(g) + ZrF₄(g) = CaF(g) + ZrF₃(g). Based on the reported equilibrium constants, the enthalpy change of this reaction is evaluated by the second and third law methods as -8.0 ± 25 and 28.0 ± 2 kcal/mol, respectively. The third law entropy drift is 20 ± 15 eu. Using the third law value and ΔH_f⁰₂₉₈ = 42.85 ± 0.3, -400.0 ± 0.5, and -65.0 ± 2 kcal/mol for Ca(g), ZrF₄(g), and CaF(g) we obtain ΔH_f⁰₂₉₈(ZrF₃, g) = -264.2 ± 5 kcal/mol, which is adopted. Employing slightly different Gibbs energy functions and ΔH_f⁰₂₉₈ values for the products and reactants, Murad and Hildenbrand (1) evaluated the third law enthalpy change of the above reaction as 28.4 ± 5 and ΔH_f⁰₂₉₈(ZrF₃, g) = -262 ± 5 kcal/mol, which are in reasonable agreement with the values adopted here.

Heat Capacity and Entropy

The molecular structure is assumed to be the same as that of TiF₃(g). The Zr-F bond distance is estimated by comparison with those for ZrF₄(g) and ZrF₂(g). The F-Zr-F bond angle is taken to be slightly larger than the F-Ti-F bond angle in the TiF₃(g) molecule. The vibrational frequencies are calculated by the valence force method (2) using force constants transferred from those for the ZrF₂(g) molecule. The three principal moments of inertia are: $I_A = I_B = 1.8280 \times 10^{-38}$ g cm², and $I_C = 2.9593 \times 10^{-38}$ g cm². The electronic levels are estimated to be three times higher than those of TiF₃(g), based on the ratio of the first splitting interval between Ti(IV) and Zr(IV), given by C. E. Moore (3). The quantum weights are assumed to be the same as those of TiF₃(g).

Bond Distance: Mg-F = [1.77] Å

Bond Angle: F-Mg-F = [135]°

Product of the Moments of Inertia: $I_{AB} I_C = [5.571 \times 10^{-11}] \text{ g.}^2 \text{ cm.}^2$

The enthalpy change, $\Delta H_f^o = 30 \text{ kcal. mole}^{-1}$, for the reaction $\text{MgF}_2(c) + \text{MgF}_2(g) = (\text{MgF}_2)_2(g)$ was determined by J. Berkowitz and J. R. Marquart, J. Chem. Phys. 9, 1853 (1962). Hence the heat of formation for $(\text{MgF}_2)_2(g)$ was calculated.

Heat Capacity and Entropy.

The molecular structure was assumed to be planar. The two Mg atoms are at the two opposite corners of a square. The other two corners of the square are occupied by two F atoms. The two remaining F atoms are situated outside the square on a straight line joining the two Mg atoms. The bond distance between Mg and F atom was estimated to be the same as that in the $\text{MgF}_2(g)$ molecule. Vibrational frequencies were estimated by comparison with those for $\text{MgF}(g)$ and $(\text{NaF})_2$. The vibrational frequencies for $(\text{NaF})_2$ were calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960). The three principal moments are 9.895×10^{-39} , 7.0235×10^{-39} , and $8.01631 \times 10^{-39} \text{ g. cm.}^2$.

Heat of Formation

Zimov et al. (1) investigated the stabilities of some molybdenum and tungsten oxyfluorides by means of mass spectrometry. These studies led to heats of formation for $\text{MoO}_2\text{F}_2(\text{g})$, $\text{WO}_2\text{F}_2(\text{g})$, and $\text{MoF}_4(\text{g})$ which were used by the authors to develop a correlation among the heats of formation of the oxides, oxyfluorides, and fluorides of Mo and W. ΔH_f° varies almost linearly with the number of oxygen atoms (1) for the series WF_6 , MoF_6 , and WO_2F_2 . Assuming a similar variation for MoF_4 , MoOF_4 , and Mo_2F_4 , we estimate $\Delta H_f^\circ(\text{MoOF}_4, \text{g}) = -320 \text{ kcal/mol}$.

Heat of formation data (2) for $\text{MoF}_6(\text{g})$, $\text{MoO}(\text{g})$, and $\text{MoO}_3(\text{g})$ have been used to derive the following average bond dissociation energies:

 $\bar{D}(\text{Mo-F}) = 107 \text{ kcal/mol}$ $\bar{D}(\text{Mo-O}) = 135 \text{ kcal/mol}$ From these data we derive $\Delta H_f^\circ(\text{MoOF}_4, \text{g}) = -271 \text{ kcal/mol}$.The heat of formation for MoOF_4 is tentatively selected as $300 \pm 30 \text{ kcal/mol}$.

Heat Capacity and Entropy

Blanchard (3) suggested that $\text{MoOF}_4(\text{g})$ possessed C_{4v} symmetry by reason of the similarity of its infrared spectra with that of XeOF_4 . X-ray diffraction studies of crystalline MoOF_4 by Edwards et al. (4, 5) support this view. The structure of the molecule is assumed to be square-pyramidal. The bond lengths are from the crystallographic studies of MoOF_4 by Edwards et al. (4, 5). Individual moments of inertia are $I_A = 27.437 \times 10^{-39} \text{ g cm}^2$, $I_B = 41.801 \times 10^{-39} \text{ g cm}^2$.

Blanchard (3) reported the following vibrational frequencies and assignments:

 $\nu_1 = 1045$, $\nu_2 = 720$, $\nu_3 = 680$, and $\nu_6 = 530 \text{ cm}^{-1}$.Similar frequencies have been reported by Edwards et al. (4) from their study of the infrared spectra of gaseous MoOF_4 .The rest of the frequencies and assignments are estimated by comparison with data for XeOF_4 (5).

Heat of Formation.

G. T. Armstrong, S. Marantz, and C. F. Coyle, National Bureau of Standards Report No. 6584, October, 1959, studied the reaction

From this reaction, they calculate the heat of formation of N₂F₄ to be -2.0 ± 2.5 kcal. mole⁻¹. The recalculated heat of formation of NH₄F(s) (see NF₂ table) differs from the value quoted in Circular 500 by 0.06 kcal. mole⁻¹. This correction would make the heat of formation of tetrafluorohydrazine more negative by 0.24 kcal. mole⁻¹. In view of the large uncertainty in the heat of formation, however, this correction was not applied.

Heat Capacity and Entropy.

The fundamental frequencies were taken from the vapor phase infrared work of J. R. Durig and R. C. Lord, Spectrochim. Acta 19, 1877 (1963). The principal moments of inertia were calculated from the rotational constants reported by D. R. Lide, Jr. and D. E. Mann, J. Chem. Phys. 31, 1129 (1959). Lide and Mann calculated the bond angles for assumed values of the NN and NF distances.

The principal moments of inertia are: I_A = 1.5051 X 10⁻³⁸ gm. cm.², I_B = 2.6315 X 10⁻³⁸ gm. cm.², I_C = 2.9836 X 10⁻³⁸ gm. cm.².

continued from the table nitrogen difluoride (NF₂) (ideal gas).

Heat Capacity and Entropy.

M. D. Harmony, R. J. Myers, L. J. Schoen, D. R. Lide, Jr., and D. E. Mann, J. Chem. Phys. 35, 1129 (1961), investigated the infrared spectrum of NF₂. They were able to assign the band center at 1074 cm.⁻¹ to the symmetric stretching mode ω₁. The absorption in the 930-940 cm.⁻¹ region was assigned to ω₃.

M. D. Harmony and R. J. Myers, J. Chem. Phys. 37, 636 (1962), performed matrix isolation experiments on NF₂. They arrived at the assignments ω₁ = 1070 cm.⁻¹, ω₂ = 573 cm.⁻¹, and ω₃ = 931 cm.⁻¹. The stretching frequencies for similar molecules in an N₂ matrix are about 5 cm.⁻¹ below the gas phase values. A comparison of the gas phase and matrix values of ω₁ show excellent agreement.

F. A. Johnson and C. B. Colburn, Inorg. Chem. 1, 431 (1962), report infrared studies on NF₂ but they draw no definite conclusions.

The gas phase value for ω₁ and the matrix values for ω₂ and ω₃ were taken to represent the fundamental vibrational frequencies of NF₂.

Harmony, Myers, Schoen, Lide, and Mann estimated the N-F distance as 1.37 Å and used this with their data to calculate an F-N-F angle of 104.2°. Using these data the moments of inertia are: I_A = 7.3728 X 10⁻³⁹ gm. cm.², I_B = 1.2035 X 10⁻³⁹ gm. cm.², I_C = 8.5763 X 10⁻³⁹ gm. cm.².

ΔH°₀ = Unknown

ΔH°_{298.15} = [-355.37 ± 6] kcal/mol

ΔH°_m = 1.219 ± 2 kcal/mol

S°_{298.15} = [42.0 ± 4] gibbs/mol

T_m = 379°K

Heat of Formation.

The heat of formation, ΔH°_f(WOF₄, c) = -355.37 kcal/mol, is calculated from that of the gas less the heat of sublimation, ΔH°_{sub} = 16.97 kcal/mol. The latter is calculated by the third law method from the vapor pressure equation determined by G. H. Cady and G. B. Hargreaves, J. Chem. Soc., 1563 (1961). The second law ΔH°_{f298} is 17.01 kcal/mol.

Heat Capacity and Entropy.

The heat capacities are estimated from those of WOCl₄(c), WO₃(c), WO₂(c), WOCl₆(c) and WF₆(c,l).

The entropy, S°₂₉₈ = 42.0 eu, is calculated from ΔS°₃₄₈ = 37.0 eu for WOF₄(c) → WOF₄(g), obtained from the second law analysis of the vapor pressure equation given by Cady and Hargreaves, loc. cit.

It is surprising that this entropy is larger than the corresponding value for WOCl₄(c) (JANAF WOCl₄(c) table dated Mar. 31, 1967). In both cases the entropies of the condensed phases are derived from the gas phase values using second law analysis of sublimation and vaporization data. The resulting entropy of melting for WOF₄, 3.2 eu, is much smaller than the value 22.4 eu for WOCl₄. This extreme difference may be a reflection of the uncertainty inherent in derivation of ΔS°_m as the difference between the values for sublimation and vaporization. If the values of ΔS°_m are correct, they suggest the possibility of an undiscovered solid state transition for WOF₄ similar to that observed for WF₆.

Melting Data.

T_m is calculated as the temperature at which the Gibbs energy of reaction WOF₄(c) → WOF₄(l) approaches zero. The difference between the heats of formation for crystal and liquid at the melting point is ΔH°_m.

O. Ruff, F. Elander, and W. Heller, Z. Anorg. Chem. 52, 256 (1907), reported the melting point as 393°K. Cady and Hargreaves, loc. cit., derived the melting point as 378°K, and the heat of fusion as 2.26 kcal/mol from vapor pressure equations for crystal and liquid. This second law value of ΔH°_m, when corrected for ΔC_p of vaporization and sublimation, is in good agreement with the value adopted in the tabulation.

TUNGSTEN OXYTETRAFLUORIDE (WOF₄)

(LIQUID)

OFW = 275.843

$$\Delta H^\circ_{298,15} = [-354.955] \text{ kcal/mol}$$

$$\Delta H_m^\circ = 1.219 \pm 2 \text{ kcal/mol}$$

$$\Delta H_v^\circ = 13.4 \text{ kcal/mol}$$

$$S^\circ_{298,15} = [42.8 \pm 4] \text{ gibbs/mol}$$

$$T_m = 379^\circ\text{K}$$

$$T_b = 460^\circ\text{K}$$

Heat of Formation.

The heat of formation, $\Delta H^\circ_{298}(\text{WOF}_4, l) = -354.955 \text{ kcal/mol}$, is calculated from that of the gas less the heat of vaporization, $\Delta H^\circ_{298} = 16.555 \text{ kcal/mol}$. The latter is calculated by the third law method from the vapor pressure equation determined by G. H. Cady and G. B. Hargreaves, J. Chem. Soc., 1563 (1961). The second law ΔH°_{298} is 16.60 kcal/mol.

Heat Capacity and Entropy.

The heat capacity is assumed to be constant at 7.25 gibbs/g-atom as suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry," Pergamon Press, New York, 1959.

The entropy, $S^\circ_{298} = 42.8 \text{ eu}$, is calculated from $\Delta S^\circ_{298} = 31.2 \text{ eu}$ for $\text{WOF}_4(l) \rightarrow \text{WOF}_4(g)$, obtained from the second law analysis of the vapor pressure equation given by Cady and Hargreaves, loc. cit.

Melting Data.

See WOF₄(c) table (Mar. 31, 1967).

Vaporization Data.

T_b is calculated as the temperature at which the Gibbs energy of reaction $\text{WOF}_4(l) \rightarrow \text{WOF}_4(g)$ approaches zero. The difference between the heats of formation for liquid and gas at the boiling point is ΔH_v° .

O. Ruff, P. Eisner and W. Heller, Z. Anorg. Chem. 52, 256 (1907), reported the boiling point as 459°K. Cady and Hargreaves, loc. cit., derived the boiling point as 459°K, and the heat of vaporization as 14.23 kcal/mol from the vapor pressure equation for the liquid. This second law value of ΔH_v° , when corrected for ΔC_p of vaporization, is in good agreement with the value adopted in the tabulation.

Tungsten Oxytetrafluoride (WOF₄)
(Ideal Gas) $\Delta H_f^\circ = 275.843$

Heat of Formation.

The heat of formation, ΔH_f° (WOF₄, g) = -338.4 kcal/mol, is the value determined mass spectrometrically by K. P. Zmbov and J. L. Margrave, Rice Univ., private communication, Mar. 1967, from equilibrium studies of

Heat Capacity and Entropy.

The molecular configuration is assumed to be a trigonal bipyramid similar to that of SOF₄(g), reported by P. L. Oggien, H. L. Roberts and L. A. Woodward.¹ The bond distances W-O and W-F are estimated to be the same as those in WO₃(g) and WF₆(g), respectively. The three principal moments of inertia are I_A = 3.509 × 10⁻³⁸, I_B = 3.698 × 10⁻³⁸ and I_C = 2.981 × 10⁻³⁸ g cm².

All vibrational frequencies are estimated by comparison with those observed in the infrared and Raman spectra for SOF₄(g),² MoOCl₄(g),³ WO₂Cl₂(g),⁴ CrO₂Cl₂(g),⁵ WO₃(g),⁶ and WF₆(g).⁷ These frequencies are not in point group order.

June 30, 1962

Lead Tetrafluoride (PbF₄) (Ideal Gas)

Mol. Wt. = 283.21

 ΔH_f^0 298.15 = [-186] kcal. mole⁻¹ ΔF_f^0 298.15 = 79.7 cal. deg.⁻¹ mole⁻¹Point group T_d

Vibrational Levels and Multiplicities

 ω_e , cm.⁻¹

564 (1)

158 (2)

570 (3)

180 (3)

Pb-F distance = 2.08 Å P-Pb-F angle = 109° 28'

 $I_{A_1, E_C} = 4.8233 \times 10^{-113}$ g.³ cm.⁶ $\sigma = 12$ Heat of Formation. ΔH_f^0 298.15 was estimated by comparison with the value of ΔH_f^0 298.15 for PbF₂(g).

Heat Capacity and Entropy. Vibrational frequencies and molecular constants were obtained from G. Nagelschen, Bull. Soc. Chim. Belg., 71, 119 (1962).

GFW = 108.058

(IDEAL GAS)

SULFUR TETRAFLUORIDE (SF₄)Point Group C_{2v}S_{298.15} = 71.83 ± 0.10 gibbs/mol

Ground State Quantum Weight = 1

Sulfur Tetrafluoride (SF₄)

(Ideal Gas)

GFW = 108.058

Dec. 31, 1960; Sept. 30, 1963

Point Group T_d
S_{298.15} = 67.433 cal. deg.⁻¹ mole⁻¹
Ground State Quantum Weight = [1]

ΔH_f^o 0 = -384.65 ± 0.19 kcal. mole⁻¹
ΔH_f^o 298.15 = -385.98 ± 0.19 kcal. mole⁻¹

Vibrational Frequencies and Degeneracies

ω, cm.⁻¹ ω_g, cm.⁻¹

800 (1) 1031 (3)
268 (2) 391 (3)

Bond Distances Si-F = 1.54 ± 0.02 Å
Bond Angle: F-Si-F = 109° 29'
Product of the Moments of Inertia: I_AI_BI_C = 7.93269 X 10⁻¹¹⁴ g.³ cm.⁶
σ = 12

Heat of Formation.

The heat of formation of SiF₄(g) was measured by direct combination of the elements in a bomb calorimeter by S. S. Wise, J. L. Margrave, H. M. Feder and W. N. Hubbard, J. Phys. Chem. 67, 815 (1963). ΔH_f^o 298.15 was found to be -385.98 ± 0.19 kcal. mole⁻¹. Heats of the reaction between SiF₄(g) and Ne(g), 1.9% HF solution, 0.4% HP solution, a solution of NaF saturated with Ne₂SiF₆, and water have been measured by A. P. Vorob'ev, V. P. Kolesov, and S. M. Skuratov, Zh. Neorg. Khim. 5, 1402 (1960). The value of ΔH_f^o 298.15 for SiF₄(g) was reported to be -372.4 ± 0.4 kcal. mole⁻¹ which was not used.

Heat Capacity and Entropy.

The vibrational frequencies used were reported by E. A. Jones, J. S. Kirby-Smith, P. J. H. Woltz, and A. H. Nielsen, J. Chem. Phys. 19, 242 (1951). The values of vibrational frequencies were given as 800(1), 285(2), 1000(3), and 431(3) for SiF₄(g) by D. M. Yost, E. M. Lassette, and S. T. Gross, J. Chem. Phys. 4, 325 (1936). The molecular data were obtained from L. Pauling and L. O. Brockway, J. Am. Chem. Soc. 57, 2684 (1935). The three principal moments of inertia are: I_A = I_B = I_C = 1.99437 X 10⁻³⁸ g. cm.²

TITANIUM TETRAFLUORIDE (TiF₄)
(CRYSTAL)

GFW = 123.8936

ΔHf°_O = -393.67 ± 0.9 kcal/mol
ΔHf°_{298.15} = -394.2 ± 0.9 kcal/mol
ΔHs°_{298.15} = 23.37 ± 0.1 kcal/mol

S°_{298.15} = 32.02 gibbs/mol
Ts = 558.6°K

Heat of Formation
The heat of formation (ΔHf°_{298.15}) of TiF₄(c) was measured using a fluorine bomb calorimeter by Greenberg et al. (1). Gross et al. (2) reported a value of -393.4 kcal/mol for ΔHf°₂₉₈. The latter measurements were not corrected for impurities in the titanium sample, thus the value reported by Greenberg et al. is adopted.

Heat Capacity and Entropy
The heat capacity of TiF₄(c) has been measured over the temperature range 6° to 304°K by Euler and Westrum (3). They obtained the value of S°₂₉₈ based on S°₁₀ = 0.11 eu. Heat capacities above 300°K are estimated from those of ZnF₄(c) (4).

Heat of Sublimation
The sublimation point is calculated as the temperature at which ΔGr° = 0 for TiF₄(c) = TiF₄(g). The heat of sublimation is obtained from the data of Hall et al. (5).

Heat of Formation

The heat of formation of TiF₄(g) is calculated from that of the crystal and the heat of sublimation, ΔH_{sub}²⁹⁸, obtained from vapor pressure measurements. E. H. Hall, J. M. Blocher, Jr., and I. E. Campbell, J. Electrochem. Soc. 105, 275 (1958), have reported extensive vapor pressure data for the reaction TiF₄(c) = TiF₄(g). Second and third law analyses of their data yielded the following results.

*Calculation based on third law ΔH_f²⁹⁸.

**Four points rejected due to failure of a statistical test.

***Eight points rejected due to failure of a statistical test.

Heat Capacity and Entropy

The interatomic distance is obtained from a correlation of the measured values for TiCl₄(g), TiBr₄(g), TiCl₃⁻², and TiF₆⁻². The principal moments of inertia are I_A = I_B = I_C = 2.724 × 10⁻³⁸ g cm².

The vibrational frequencies are estimated by a valence force field treatment of estimated force constants. The force constants are estimated from a correlation with the constants of CF₄, SiF₄, CCl₄, SiCl₄, CBr₄, SiBr₄, TiCl₄ and TiBr₄. The resulting frequencies are adjusted so that calculations of ΔH_f²⁹⁸ by both second and third law methods are in agreement.

GFW = 167.2136

(CRYSTAL)

ZIRCONIUM TETRAFLUORIDE (ZrF_4)

Zirconium Tetrafluoride (ZrF_4)

(Crystal) GFW = 167.2136

$S_{298.15}^\circ = 25.024 \pm 0.05$ gibbs/mol
 $T_f(\alpha + \beta) = 723^\circ\text{K}$
 $T_m = 1205 \pm 2^\circ\text{K}$
 $T_b = 1179^\circ\text{K}$

$\Delta H_f^\circ = -455.44 \pm 0.25$ kcal/mol
 $\Delta H_{298.15}^\circ = -456.80 \pm 0.25$ kcal/mol
 $\Delta H_c^\circ = \text{Unavailable}$
 $\Delta H_m^\circ = 15.35 \pm 0.10$ kcal/mol
 $\Delta H_s^\circ = 51.64$ kcal/mol
 $\Delta H_{298.15}^\circ = 56.80$ kcal/mol

Heat of Formation

The heat of formation of zirconium tetrafluoride was measured by direct combination of the elements in a bomb calorimeter by Greenberg, Settle, Feder, and Hubbard (1). The reported value $\Delta H_{298}^\circ(\text{ZrF}_4, c) = -456.80 \pm 0.25$ kcal/mol is adopted.

Heat Capacity and Entropy

The low temperature heat capacities in the temperature range 5 to 307°K were determined by adiabatic calorimetry by Westrum (2). Using these low temperature Cp data the value of S_{298}° is derived as 25.024 ± 0.05 eu, based on $S_{10}^\circ = 0.0074$ eu. McDonald, Sinke, and Stull (3) measured the high temperature enthalpies of $\text{ZrF}_4(c)$ at temperatures 283.9 - 1275.8°K in a copper block drop calorimeter. Smith, Miller, and Taylor (4) used a Bunsen ice calorimeter for the heat-content measurements in the temperature range 273 - 1150°K. These two sets of enthalpy data are not in good agreement. It is possible that the discrepancies are due to the difference in crystal structure of the samples used (see "Transition Data" for more information). In order to join smoothly with the low temperature heat capacities at 298°K, the high temperature heat capacities derived from the enthalpy data of McDonald, Sinke, and Stull (3) are adopted. The Cp values above 1200°K are obtained by smooth extrapolation.

Transition Data

Zirconium tetrafluoride has three crystal structures (α , β and γ) and one amorphous form (δ). From a differential thermal analysis of $(\text{NH}_4)_3\text{ZrF}_7$ sample, Chretien and Gaudreau (5) found that $\text{ZrF}_4(c)$ has an α and β form with a transition temperature above 678°K. They also determined the densities of α (tetragonal) and β (monoclinic) as 4.25 ± 0.05 and 4.61 ± 0.03 gm/cc, and a transition temperature as $T(\alpha + \beta) = 723^\circ\text{K}$ (7). It was observed that the α phase is unstable at all temperatures above 298°K. In reference (5), Gaudreau mentioned the methods of preparation of the four varieties of ZrF_4 and indicated that α -, γ -, and amorphous ZrF_4 transform irreversibly to β - ZrF_4 at 723 - 773°K.

The ZrF_4 sample employed by McDonald, Sinke, and Stull (3) for enthalpy measurement was prepared by dissolving hafnium-free zirconium metal in 48% aqueous HF, and the resulting solution was evaporated to dryness. The crystalline product was heated slowly to 773°K in a platinum boat in a glow current of anhydrous HF. X-ray diffraction showed only crystalline ZrF_4 . Wet analysis indicated 54.6% Zr (theory 54.55) and 44.9% F (theory 45.45). Due to the above facts we are uncertain whether the sample prepared is a mixture of α and β forms or a pure $\text{ZrF}_4(\beta)$. Smith, Miller, and Taylor (4) obtained their ZrF_4 sample from the Oak Ridge National Laboratories, Oak Ridge, Tenn. Since the method of preparation of the compound is unavailable from the report, we do not know what kind of sample they used for measurement.

Because of the above complicated situation, we emphasize that this $\text{ZrF}_4(c)$ table is not strictly a α , β -combined phase table. However, the differences in the calculated functions are probably not significant.

Melting Data

T_m and ΔH_m° are taken from McDonald, Sinke, and Stull (3). The values were obtained under conditions greater than one atmosphere.

Sublimation Data

The sublimation temperature (T_b) is calculated as the temperature at which the Gibbs energy change of the process $\text{ZrF}_4(c) = \text{ZrF}_4(g)$ approaches zero. The difference between ΔH_{298}° for $\text{ZrF}_4(g)$ and $\text{ZrF}_4(c)$ at 1179 and 298°K is ΔH_s° and ΔH_{298}° , respectively.

Since this sublimation temperature is lower than the melting point, the ZrF_4 sublimates before it melts.

Vibrational Frequencies and Degeneracies

Bond Distance: Zr-F = 1.94 ± 0.02 Å
 Bond Angle: F-Zr-F = 109.47°
 Product of the Moments of Inertia: $I_A I_B I_C = 3.17347 \times 10^{-213}$ g cm⁶
 $\sigma = 12$

Heat of Formation
 The vapor pressures of ZrF₄(c) in the temperature range 617-1150°K were determined by many investigators using various methods. Based on the reported vapor pressure data, the corresponding heats of sublimation are evaluated by the second and third law methods. Using the third law ΔH_{298}° and ΔH_{298}° (ZrF₄, c) = -456.8 kcal/mol, the heats of formation at 298°K for ZrF₄(g) are evaluated. The results are presented in the table below. The values of ΔH_{298}° (ZrF₄, g) listed in the last column of this table are in excellent agreement which indicate that the estimated missing vibrational frequencies ν_1 and ν_2 are reasonable. The heat of formation at 298°K for ZrF₄(g) is adopted as -400.0 kcal/mol.

Heat Capacity and Entropy

The molecular structure of ZrF₄(g) has been studied by electron diffraction by Spidonov (11). The configuration was found to be a regular tetrahedron with interatomic distance Zr-F = 1.94 ± 0.02 Å and F-Zr-F bond angle = 109.47° which are adopted. Employing the estimated interaction coefficients and interatomic distance Zr-F = 1.85 Å, Godnev, Aleksandrova, and Rigina (12) calculated three vibrational frequencies for ZrF₄(g) as $\nu_1 = 600 - 725$, $\nu_2 = 150 - 200$, and $\nu_4 = 180 \pm 230$ cm⁻¹. Buchler, Berkowitz, and Dugre (13) observed the infrared spectra of some group IV halides and assigned $\nu_3 = 668$ and $\nu_4 = 190 \pm 20$ cm⁻¹ for ZrF₄(g). The frequency ν_3 has also been reported as 670 cm⁻¹ (14). The values of ν_3 and ν_4 adopted here are those reported by Buchler, Berkowitz, and Dugre (13). The adopted ν_1 is obtained by correlating the corresponding frequencies of the tetrafluorides of C, Pb, Si, Ti and Ge with their respective interatomic distances. ν_2 is calculated from ν_1 , ν_3 and ν_4 using the relationship $(15) \nu_1 \nu_2 \nu_3 \nu_4 = \frac{2}{3} (1 - \frac{4}{Z})$, where F and Zr are gram atomic weights of fluorine and zirconium, respectively. The three principal moments of inertia are $I_A = I_B = I_C = 3.166 \times 10^{-38}$ g cm².

Vibrational Frequencies and Degeneracies

ω_e , cm ⁻¹	ω_e , cm ⁻¹	ω_e , cm ⁻¹
710 (1)	604 (1)	631 (2)
616 (1)	[257] (1)	372 (2)
318 (1)	276 (1)	190 (2)

Bond Distance: I-F(equatorial) = 1.86 Å I-F(axial) = 1.75 Å

Bond Angle: F-I-F = 90°

Product of the Moments of Inertia: I_AI_BI_C = [4.10383 × 10⁻¹¹³] g³ cm⁶

Heat of Formation

The adopted value is derived from calorimetric data of Settle et al. (1) for the combustion of iodine in fluorine. Although the combustions gave various mixtures of IF₃ and IF₅, the proportions ranged up to almost pure pentafluoride. Reduction of the data gave ΔH_f⁰ = -210.80 ± 0.32 kcal/mol for IF₅(g) at 298.15 K. The result is essentially independent of the heptafluoride.

Comparison values of -208.9 ± [2.1] and -208.8 ± [2.1] kcal/mol may be obtained from calorimetric data of Woolf (2) for hydrolysis in water and in aqueous KOH. Uncertainties for these values include large contributions due to auxiliary data (3).

In particular, we estimate lower limits of ±0.8 kcal/mol for ΔH_f⁰ of HIO₃(1250 H₂O) and KIO₃(1250 H₂O) by comparison with recent data (4).ΔH_f⁰ for the ideal gas is derived from that of the liquid by use of ΔH_v⁰ = 9.96 kcal/mol at 298.15 K. ΔH_v⁰ was derived by Osborne et al. (5) from measurements of vapor pressure and the second virial coefficient.

Heat Capacity and Entropy

There is no published structural determination for gaseous IF₅, but spectral data are consistent with C_{4v} symmetry and a configuration which is approximately a square pyramid. It is uncertain whether the iodine is located above, in, or below the base of the pyramid and whether or not the axial and equatorial I-F distances are equal. We adopt the structure used by Begun et al. (7) in correlation of infrared and Raman spectra of BrF₅, IF₅, ClF₅, and XeOF₄ by normal coordinate analysis. In this structure the axial bond length is shorter than the equatorial length and the values are close to those observed experimentally for IF₇. The iodine is presumed to be in the base of the pyramid. Simplified Hückel-molecular-orbital calculations (8) predict that C_{4v} is the most stable symmetry, that the axial bond is shorter, and that the equatorial fluorines are distorted toward the axial fluorine. It is not clear to what extent these predictions depend on the simplified HMO model used in the calculations. Begun et al. (7) note that the normal coordinate calculations are insensitive to changes in the bond angles. Principal moments are I_A = I_B = 30.66 × 10⁻³⁹ and I_C = 43.65 × 10⁻³⁹ g cm².Vibrational frequencies are based on the assignments of Begun et al. (7) as modified by the vapor-phase Raman spectra observed by Selig (6). Location of the band center of ν₃ (4200 cm⁻¹) is difficult, so we substitute the liquid value of 190 cm⁻¹. The Raman-active fundamental ν₅ is not observed for IF₅, or any of the similar molecules, so its value is taken from the calculations (7).Osborne et al. (5) used calorimetric data at low temperatures to derive S⁰ = 57.96 ± 0.06 gibbs/mol for the liquid at 330 K. Combining this with ΔS⁰ based on their vapor pressure equation, the authors obtained S⁰ = 83.06 ± 0.20 gibbs/mol for the ideal gas at 330 K. The corresponding value from this table (89.50) is lower by 0.58 gibbs/mol. Part of this difference arises from uncertainties in ν₅, ν₃, and the product of the moments of inertia. We estimate this uncertainty at about 0.5 gibbs/mol. Another source of minor uncertainty is the neglect of anharmonicity in the calculations.

Vibrational Frequencies and Degeneracies

ω_e , cm ⁻¹	ω_e , cm ⁻¹	ω_e , cm ⁻¹
710 (1)	604 (1)	631 (2)
616 (1)	[257] (1)	372 (2)
318 (1)	276 (1)	190 (2)

Bond Distance: I-F(equatorial) = 1.86 Å I-F(axial) = 1.75 Å

Bond Angle: F-I-F = 90°

Product of the Moments of Inertia: I_AI_BI_C = [4.10383 × 10⁻¹¹³] g³ cm⁶

Heat of Formation

The adopted value is derived from calorimetric data of Settle et al. (1) for the combustion of iodine in fluorine. Although the combustions gave various mixtures of IF₃ and IF₅, the proportions ranged up to almost pure pentafluoride. Reduction of the data gave ΔH_f⁰ = -210.80 ± 0.32 kcal/mol for IF₅(g) at 298.15 K. The result is essentially independent of the heptafluoride.

Comparison values of -208.9 ± [2.1] and -208.8 ± [2.1] kcal/mol may be obtained from calorimetric data of Woolf (2) for hydrolysis in water and in aqueous KOH. Uncertainties for these values include large contributions due to auxiliary data (3).

In particular, we estimate lower limits of ±0.8 kcal/mol for ΔH_f⁰ of HIO₃(1250 H₂O) and KIO₃(1250 H₂O) by comparison with recent data (4).ΔH_f⁰ for the ideal gas is derived from that of the liquid by use of ΔH_v⁰ = 9.96 kcal/mol at 298.15 K. ΔH_v⁰ was derived by Osborne et al. (5) from measurements of vapor pressure and the second virial coefficient.

Heat Capacity and Entropy

There is no published structural determination for gaseous IF₅, but spectral data are consistent with C_{4v} symmetry and a configuration which is approximately a square pyramid. It is uncertain whether the iodine is located above, in, or below the base of the pyramid and whether or not the axial and equatorial I-F distances are equal. We adopt the structure used by Begun et al. (7) in correlation of infrared and Raman spectra of BrF₅, IF₅, ClF₅, and XeOF₄ by normal coordinate analysis. In this structure the axial bond length is shorter than the equatorial length and the values are close to those observed experimentally for IF₇. The iodine is presumed to be in the base of the pyramid. Simplified Hückel-molecular-orbital calculations (8) predict that C_{4v} is the most stable symmetry, that the axial bond is shorter, and that the equatorial fluorines are distorted toward the axial fluorine. It is not clear to what extent these predictions depend on the simplified HMO model used in the calculations. Begun et al. (7) note that the normal coordinate calculations are insensitive to changes in the bond angles. Principal moments are I_A = I_B = 30.66 × 10⁻³⁹ and I_C = 43.65 × 10⁻³⁹ g cm².Vibrational frequencies are based on the assignments of Begun et al. (7) as modified by the vapor-phase Raman spectra observed by Selig (6). Location of the band center of ν₃ (4200 cm⁻¹) is difficult, so we substitute the liquid value of 190 cm⁻¹. The Raman-active fundamental ν₅ is not observed for IF₅, or any of the similar molecules, so its value is taken from the calculations (7).Osborne et al. (5) used calorimetric data at low temperatures to derive S⁰ = 57.96 ± 0.06 gibbs/mol for the liquid at 330 K. Heat of Formation

Gross, Hayman, and Stuart (1) measured the heat of combustion of α-white phosphorus in fluorine at 25°C. They reported a heat of formation of -381.4 ± 0.8 kcal/mol (based on α-white phosphorus standard state) calculated from their combustion studies. Similar combustion studies were performed by O'Hare and Hubbard (2). They reported a heat of formation of -380.8 ± 0.3 kcal/mol (α-white phosphorus standard state), which is in excellent agreement with the work of Gross et al. (1). An average value of -381.1 ± 0.5 kcal/mol is adopted for this tabulation. Converting to the P(red, V) standard state with a ΔH trans = 4.2 ± 0.2 kcal/mol (3), we derive, ΔH_f[°](PF₅, g) = -376.9 ± 0.7 kcal/mol.

Heat Capacity and Entropy

The molecular structure and bond lengths given above for PF₅ were recently determined by Hansen and Bartell (4) from electron-diffraction studies. These results indicate that PF₅ has a trigonal bipyramidal structure with nonequivalent axial and equatorial bonds. Wyatt et al. (5) determined rotational constants for PF₅ from a study of the infrared vibration-rotation band contour of the ν₄ (575 cm⁻¹) fundamental. Their analysis led to the following P-F bond lengths which are in excellent agreement with the electron-diffraction results: $r_{\text{ax}} = 1.534 \pm 0.024 \text{ \AA}$ and $r_{\text{eq}} = 1.581 \pm 0.025 \text{ \AA}$. Individual moments of inertia, calculated from the rotational constants given by Wyatt et al. (5) and adopted for this table, are $I_A = 2.230 \times 10^{-38} \text{ g cm}^2$ and $I_B = I_C = 2.690 \times 10^{-38} \text{ g cm}^2$. The electron diffraction data lead to a product of moments of inertia of $1.604 \times 10^{-113} \text{ g cm}^6$.

Several recent infrared and Raman studies (6, 7, and 8) have been reported for PF₅. These data are in good agreement except for the ν₇ fundamental. Griffiths et al. (6) originally assigned this fundamental to the 126 cm⁻¹ band observed in their infrared spectra. Hoskins (7) later attributed this band to one of the pure rotational lines of hydrogen fluoride, which he felt was present in the sample as an impurity. Further work by Griffiths (10) on the pressure dependence of the infrared spectra of PF₅ indicated that the missing fundamental should be assigned to the weak band at 301 cm⁻¹. Deiters and Holmes (11) recently showed that this band is not a fundamental of PF₅ but a difference band (ν₃-ν₂). Very recently, Levin (8) investigated the Raman spectra of solid phosphorus pentafluoride and assigned the ν₇ fundamental to the 179 cm⁻¹ band. Also, Beattie et al. (12) investigated the Raman spectra of PF₅ in the gas phase at 25°C and 125°C and assigned the ν₇ fundamental to 175 cm⁻¹ band which is in excellent agreement with Levin's assignment (8). The fundamental vibrational frequencies of Holmes and Lord (7) are adopted along with Levin's assignment (8) of the ν₇ fundamental (179 cm⁻¹).

Molybdenum Hexafluoride (MoF₆)

(Liquid)

GFW = 209.930

MOLYBDENUM HEXAFLUORIDE (MoF₆)

(LIQUID)

GFW = 209.930

 $S_{298.15}^{\circ} = 62.07 \pm 0.08$ gibbs/mol $\Delta H_f^{\circ} = -379.080 \pm 0.3$ kcal/mol $T_m = 290.76^{\circ}\text{K}$ $\Delta H_m^{\circ} = 1.034 \pm 0.001$ kcal/mol $T_b = 307.04^{\circ}\text{K}$ (δ + real gas, $P = 1$ atm, $f = 0.956$ atm) $\Delta H_v^{\circ} = 6.512 \pm 0.04$ kcal/mol $T_b = 308.0^{\circ}\text{K}$ (δ + ideal gas, $P = f = 1$ atm) $\Delta H_v^{\circ} = 6.562$ kcal/mol

Heat of Formation

The adopted heat of formation, $\Delta H_f^{\circ}(\text{MoF}_6, l) = -379.080 \pm 0.3$ kcal/mol, is calculated from the heat of formation of the gas, $\Delta H_f^{\circ}(\text{MoF}_6, g) = -372.4 \pm 0.2$ kcal/mol (1), and the heat of vaporization, $\Delta H_v^{\circ} = 6.680 \pm 0.03$ kcal/mol at 298.15°K . The value for the heat of vaporization is obtained from a third law analysis of the vapor pressure data reported by Osborne et al. (2).

Myers and Brady (3) determined calorimetrically $\Delta H_r = -154.7$ kcal/mol for the hydrolysis reaction:

Heats of formation of Na_2MoO_4 and NaF in the final solution were determined from the following two auxiliary heat of reaction measurements:

 $\Delta H_r = -17.6$ kcal/mol $\Delta H_r = +0.09$ Kcal/mol

Combining these results with the following heat of formation data:

 $\Delta H_f^{\circ}(\text{Na}_2\text{O}_3, c) = -178.1 \pm 0.1$ kcal/mol (4) $\Delta H_f^{\circ}(\text{NaF}, c) = -137.52 \pm 0.2$ kcal/mol (5) $\Delta H_f^{\circ}(\text{NaF} \cdot 500 \text{H}_2\text{O}) = -112.12$ kcal/mol (6)

we derive $\Delta H_f(\text{Na}_2\text{MoO}_4, \text{ in soln.}) = -351.6$ kcal/mol and $\Delta H_f(\text{NaF}, \text{ in soln.}) = -137.4$ kcal/mol. These data, when combined with the results for the hydrolysis of MoF_6 , lead to $\Delta H_f^{\circ}(\text{MoF}_6, l) = -397.6$ kcal/mol. This result is not in agreement with the adopted value.

Heat Capacity and Entropy

The heat capacity measurements for liquid MoF_6 by Osborne et al. (2) are adopted. Outside the observed range C_p was extrapolated linearly with temperature. $S_{298.15}^{\circ}$ is evaluated from the thermal data of Osborne et al. (2) and the third law of thermodynamics. They reported heat capacity data in the range $5^{\circ}\text{--}350^{\circ}\text{K}$ with $S_{5^{\circ}\text{K}} = 0.024$ gibbs/mol.

Melting Data

Melting point and heat of melting data for MoF_6 have been reported by several investigators. These results are summarized below.

Investigator	Method	Melting Point $^{\circ}\text{K}$	ΔH_m° kcal/mol
Osborne et al. (2)	Calorimetric	290.76 ± 0.02	1.034 ± 0.001
Brady et al. (2)	Calorimetric	290.7	1.059 ± 0.010
Cady and Hargreaves (8)	Vapor Pressure	290.55	$1.00 \pm 0.03^*$
Ruff and Ascher (9)	Vapor Pressure	290.65	$1.31 \pm 0.2^*$

* This value is the difference between the 2nd law heat of sublimation corrected for ΔC_p of the process and the adopted heat of vaporization calculated at 290.76°K with $(H_{290.76}^{\circ} - H_{298.15}^{\circ})$ for the vapor and liquid.

The value $\Delta H_m^{\circ}_{290.76} = 1.034 \pm 0.001$ kcal/mol from Osborne et al. (2) is adopted.

Vaporization Data

Second and third law analyses of various sets of vapor pressure data (2, 8, 9) are summarized below. Corrections for nonideality of the vapor have been calculated from the second virial coefficient equation reported by Osborne et al. (2).

Investigator	Temp. Range $^{\circ}\text{K}$	No. of Points	Boiling Point $^{\circ}\text{K}$	ΔH_v° kcal/mol
Osborne et al. (2)	291.15 - 320.15	21	307.04	2nd law* 6.690
Cady and Hargreaves (8)	290.55 - 307.15	Equation	307.15	3rd law 6.680
Ruff and Ascher (9)	290.65 - 294.85	4	308.15	6.74
* with $\Delta C_p = -11.77$ gibbs/mol				5.99

The value $\Delta H_v^{\circ}_{298} = 6.680 \pm 0.03$ ($\Delta H_v^{\circ}_{297.04} = 6.512 \pm 0.04$) kcal/mol, determined from the vapor pressure data of Osborne et al. (2), is adopted in the tabulation. The temperature at which $\Delta G_v^{\circ} = 0$ is 308.0°K and the corresponding $\Delta H_v^{\circ} = 6.562$ kcal/mol.

ω , cm ⁻¹	g , cm ⁻¹
741 (1)	262 (3)
643 (2)	312 (3)
741 (3)	122 (3)

Bond Distance: Mo-F = 1.84 ± 0.02 Å
 Bond Angle: F-Mo-F = 90°
 Product of Moments of Inertia: I_AI_BI_C = 7.771 × 10⁻¹¹³ g cm⁶
 $\sigma = 24$

Heat of Formation

Settle et al. (1) measured the heat of formation of gaseous MoF₆ by direct combination of its elements in a nickel bomb calorimeter. Their result was $\Delta H_f^\circ(\text{MoF}_6, g) = -372.4 \pm 0.2 \text{ kcal/mol}$. This value is adopted in the tabulation.

Heat Capacity and Entropy

Tanner and Duncan (2) investigated the Raman spectra of liquid MoF₆, and their results indicated that the structure of the molecule was a regular octahedron with O_h symmetry rather than an unsymmetrical structure as reported by Braune and Pinnow (3) from electron diffraction studies. The Mo-F bond length is from the electron diffraction studies of Nazarian (4). Individual moments of inertia are I_A = I_B = I_C = 4.268 × 10⁻³⁸ g cm².

Several infrared (5, 6, 7) and Raman (8, 9) studies of MoF₆ have been reported. The vibrational frequencies reported for MoF₆ from these studies are in good agreement except for the infrared and Raman inactive ν_6 vibration. Burke et al. (5) and Hellberg et al. (8) derived $\nu_6 = 234 \text{ cm}^{-1}$, while Claassen et al. (7) assigned $\nu_6 = 130 \text{ cm}^{-1}$ and Gault (6) assigned $\nu_6 = 240 \text{ cm}^{-1}$. Weinstock and Goodman (9) recently analyzed the infrared and Raman data for MoF₆ and assigned $\nu_6 = 122 \text{ cm}^{-1}$.

Osborne et al. (10) calculated $S^\circ = 62.06 \pm 0.06 \text{ gibbs/mol}$ for liquid MoF₆ at 298.15°K from their low temperature thermal data. Combining this with ΔS° , they obtained $S^\circ = 83.75 \pm 0.10 \text{ gibbs/mol}$ for the ideal gas at 298.15°K. Accepting the assignments of Weinstock and Goodman (9), we calculate $S_{298.15}^\circ = 83.76 \text{ gibbs/mol}$, which is in excellent agreement with the thermal results. The other assignments given above for ν_6 all lead to ideal gas entropies that are lower than the thermal results. Therefore, the assignments given by Weinstock and Goodman (9) are adopted here.

Heat of Formation.

P. A. G. O'Hare, J. L. Settle, and W. N. Hubbard, Preprint of Paper XIV on Fluorine Bomb Calorimetry, July, 1965, measured the enthalpy of combustion of rhombic sulfur in fluorine. Their result yields ΔH°_f 298 = -291.79 ± 0.24 kcal. mole⁻¹. P. Gross, C. Hayman, and D. L. Levi, XVIII Intern. Congr. Pure and Appl. Chem., Abstr. 1, 90 (1959), reported -289.5 kcal. mole⁻¹ also based on direct combination of the elements. O'Hare, Settle, and Hubbard mentioned a private communication from Dr. Gross indicating -289.5 kcal. mole⁻¹ may be in error due to oxygen in the fluorine used and preliminary results of a redetermination are in better agreement with -291.79 kcal. mole⁻¹. D. M. Yost and W. H. Claussen, J. Am. Chem. Soc. 55, 887 (1933) determined -282 kcal. mole⁻¹, again by direct reaction of the elements, which now appears too low. The work of O'Hare et al., loc. cit., is adopted.

Heat Capacity and Entropy.

V. C. Ewing and L. E. Sutton, Trans. Faraday Soc. 59, 124 (1963) measured the bond length adopted here by the electron diffraction technique. Earlier less accurate work by the same method by H. Braune and S. Knoke, Z. physik. Chem. 221, 297 (1933) and L. O. Brockway and L. Pauling, Proc. Nat. Acad. Sci. USA 19, 68 (1933) is in agreement within experimental error. T. E. Morsy, Ber. Bunsenges Physik. Chem. 68, 277 (1964) reviewed the literature on Raman and infrared spectra. Frequencies given here differ slightly from his selection because more weight was given to the Raman frequencies of C. W. Gullikson, J. R. Nielsen, and A. T. Stair, Jr., J. Mol. Spectroscopy 1, 151 (1957). Calculated functions by Moray loc. cit. are in reasonable agreement with the present work.

A. Eucken and E. Schröder, Z. physik. Chem. 41B, 307 (1938) measured low temperature thermal data from which K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592 (1961) calculated S°₂₉₈ = 70.3 ± 0.7 cal. mole⁻¹ deg.⁻¹ which agrees within experimental error with the spectroscopic result.

The three principal moments of inertia are I_A = I_B = I_C = 3.0863 X 10⁻³⁸ g. cm.²

$\Delta H_{298}^{\circ} = 59.564 \pm 0.2$ gibbs/mol
 $T_m = 275.2^{\circ}\text{K}$
 $T_b = 290.5^{\circ}\text{K}$

$\Delta H_{298}^{\circ} = -417.87 \pm 0.5$ kcal/mol
 $\Delta H_m^{\circ} = 0.980$ kcal/mol
 $\Delta H_v^{\circ} = 6.465 \pm 0.08$ kcal/mol

Heat of Formation.

The adopted heat of formation, -417.87 kcal/mol, is calculated from the chosen $\Delta H_{290.3}^{\circ} = 6.465 \pm 0.08$ kcal/mol with $\Delta H_{298}^{\circ}(\text{WF}_6, \text{g}) = -411.5 \pm 0.4$ kcal/mol using all JANAP functions. The value of $\Delta H_{290.3}^{\circ}$ is obtained by corrected 2nd law analysis of vapor pressure data^{6,7,8} which are given in the vaporization section of this table.

O. E. Myers and A. P. Brady¹ measured calorimetrically $\Delta H_{298}^{\circ} = -150.1$ kcal/mol for the reaction $\text{WF}_6(1) + 6 \text{ NaOH}(500\text{H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(4900\text{H}_2\text{O}) + 6 \text{ NaF}(500 \text{H}_2\text{O})$. V. I. Spitsyn and N. N. Pataukova² measured calorimetrically $\Delta H_{298}^{\circ} = -13.8$ kcal/mol for the reaction $\text{WO}_3(\text{c}) + 2 \text{ NaOH}(50\text{H}_2\text{O}) \rightarrow \text{Na}_2\text{WO}_4(4200\text{H}_2\text{O}) + \text{H}_2\text{O}(1)$. Based on these data and auxiliary data for $\text{NaOH}(\text{aq})$ ^{3,9}, $\text{NaF}(\text{aq})$ ^{3,10} and $\text{Na}_2\text{WO}_4(\text{aq})$ ⁴, we obtain $\Delta H_{298}^{\circ} = -136.2$ kcal/mol for $\text{WF}_6(1) + 6 \text{ NaOH}(500\text{H}_2\text{O}) \rightarrow \text{WO}_3(\text{c}) + 3 \text{ H}_2\text{O}(1) + 6 \text{ NaF}(500\text{H}_2\text{O})$. This leads to $\Delta H_{298}^{\circ}(\text{WF}_6, 1) = -416.9 \pm 1$ kcal/mol which is in good agreement with the value adopted.

Heat Capacity and Entropy.

The heat capacity, 40.5 gibbs/mol, is obtained from a graph of the Cp versus temperature curve determined calorimetrically by E. F. Westrum, Jr.⁵
 The entropy, $S_{298}^{\circ} = 59.564$ eu, is calculated from the chosen $\Delta H_{290.3}^{\circ} = 6.465$ kcal/mol with $S_{298}^{\circ}(\text{WF}_6, \text{g}) = 81.504$ eu using all JANAP functions.

Melting Data.

Melting point and heat of melting have been reported by the following investigators, and their results are summarized below. Ruff and Ascher's value, 2.40 kcal/mol, is too high because they did not know of the existence of a solid-solid transition⁵ at 264.7°K with $\Delta H^{\circ} = 2.087$ kcal/mol. Westrum's data are adopted in the tabulation.

Investigator	Method	Melting Point (°K)	ΔHm° (kcal/mol)
Westrum ⁵	Calorimetric	275.2	0.980
Ruff and Ascher ⁷	Vapor pressure	275.4	2.400*
Barber & Cady ⁸	Warming curve	275.1	0.500
Cady & Hargreaves ⁶	Vapor pressure	275.2	0.420*

*This value is the difference between the 2nd law heats of sublimation and vaporization without correction for ΔCp° for both processes.

Vaporization Data.

Second law analyses of the data^{6,7,8}, neglecting corrections for nonideality of the vapor, are summarized below. The value of $\Delta H_{298}^{\circ} = 6.37$ kcal/mol ($\Delta H_{290.3}^{\circ} = 6.465$ kcal/mol) is selected in the tabulation.

Investigator	Temp. Range (°K)	No. of Points	Boiling Point (°K)	ΔHv° ₂₉₈ ° (kcal/mol)	ΔSv° ₂₉₈ ° (eu)
Ruff and Ascher ⁷	275 - 287.5	6	290.7 ± 0.2	6.50 ± 0.12	21.70
Barber and Cady ⁸	285 - 324.5	16	290.2 ± 0.05	6.37 ± 0.01	21.94
Cady and Hargreaves ⁶	275 - 290	Equation	290.3 ± 0.05	6.12	21.09

*From second law analysis using ΔCp° = -12.4 gibbs/mol

Bond Distance: W-F = 1.83 Å

Bond Angle: F-W-F = 90°

Product of the Moments of Inertia: I_AI_BI_C = 7.54576 x 10⁻¹¹³ g³ cm⁶

Heat of Formation

P. A. G. O'Hare and W. N. Hubbard, J. Phys. Chem. **70**, 3353 (1966), determined the heat of formation, ΔH_f⁰₂₉₈(WF₆g) = -411.5 ± 0.4 kcal/mol, by combustion of tungsten in fluorine in a bomb calorimeter. This value is adopted in the tabulation.

Heat Capacity and Entropy

The molecular configuration and vibrational frequencies were obtained from the infrared and Raman spectroscopic studies by J. Gaunt¹, T. G. Burke, D. F. Smith and A. H. Nielsen²; K. Tanner and A. B. P. Duncan³.
The bond distance was reported by H. H. Claassen⁴, based on the preliminary result of V. Schomaker, M. Kimura and B. Weinstein⁵ who determined the bond distance by electron diffraction. J. Gaunt⁶ derived W-F = 1.89 Å from correlations with other hexafluorides and a valence force constant calculation. The three principal moments of inertia are I_A = I_B = I_C = 4.22572 x 10⁻³⁸ g cm².

Heat of Formation

Settle et al. (1) derived $\Delta H_f^\circ = -229.7 \pm 0.6 \text{ kcal/mol}$ for IF₇(g) at 298.15 K from treatment of their calorimetric data on combustion of iodine in fluorine. The combustion products, consisting of mixtures of IF₅ and IF₃, were expanded, treated to remove excess fluorine, and then hydrolyzed. The solutions were analyzed for iodate and the sum of iodate plus periodate. Since the recovery of iodine was not complete (about 70 to 98%), it was necessary to try various assumptions about the form of the unrecovered iodine. Consistent results were obtained only by assigning the unrecovered iodine to IF₇, the less volatile product. This treatment indicated that IF₇ was formed in yields ranging from about 1 to 70%.

ΔH_f° for the reaction IF₇(g) + IF₅(g) + F₂(g) may be checked via equilibrium data (2). Using six points read from Fig. 2 of Bernstein and Katz, we obtain $\Delta H_f^\circ(3\text{rd law}) = 29.36 \pm 0.2 \text{ kcal/mol}$ and $\Delta H_f^\circ(2\text{nd law}) = 29.53 \pm 0.7 \text{ kcal/mol}$, both at 298.15 K. The entropy test, $\Delta S_f^\circ(2\text{nd law}) - \Delta S_f^\circ(\text{JANAF Functions}) = 0.3 \pm 1.4 \text{ gibbs/mol}$, indicates consistency with the JANAF functions. Combination of $\Delta H_f^\circ(3\text{rd law})$ with ΔH_f° for IF₅(g) yields $\Delta H_f^\circ(\text{IF}_7, g) = -230.2 \pm 0.6 \text{ kcal/mol}$. In deriving the uncertainty, we assume that $\Delta H_f^\circ(3\text{rd law})$ is uncertain by $\pm 0.5 \text{ kcal/mol}$ due to an estimated uncertainty of about 1.0 gibbs/mol in the JANAF value of ΔS_f° at 500 K.

Heat Capacity and Entropy

Recent evidence favors D_{5h} symmetry and a pentagonal bipyramidal structure for the heptafluoride. Claassen et al. (3) review the earlier debate about structures of lower symmetry. They provide convincing evidence of D_{5h} symmetry from the first observation of Raman spectra of the vapor state and re-examination of the infrared spectra. Their data-including five fundamentals in Raman (two polarized), five fundamentals in infrared, no coincidences between Raman and infrared, and one fundamental inactive--are consistent only with D_{5h} symmetry. This is confirmed by Falconer et al. (4) who interpret their electric-deflection experiments as indicating a symmetry-forbidden dipole moment. Extended Huckel-molecular-orbital calculations (5) also predict D_{5h} symmetry. The adopted structural parameters are from our approximate analysis of the electron-diffraction data of Thompson and Bartell (6). The authors gave a radial distribution curve and suggested only a gross (unrefined) structure because of the probable presence of a fluorocarbon impurity in their sample. Principal moments of inertia are $I_A = I_B = 46.83 \times 10^{-39} \text{ g cm}^2$ and $I_C = 84.57 \times 10^{-39} \text{ g cm}^2$.

Observed vibrational fundamentals are from Claassen et al. (3). The inactive fundamental is estimated from the calculations of Khanna (7).

 $\Delta H_{f,298.15}^{\circ} = 99.5 \pm 0.4$ kcal. mole⁻¹

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The heat capacity below 298°K. was obtained by smoothing graphically the data of G. Duyckaerts, *Physica*, 6, 401 (1939) and W. H. Keesom and B. Kurrelmeyer, *Physica*, 6, 633 (1939) over the range 1° - 20°K.; P. E. Simon and R. C. Swain, *Z. Physik. Chem.* 28B, 189 (1935) (30-220°K.), A. Bucken and H. Werth, *Z. Anorg. Chem.* 188, 152 (1930) (17-206°K.) and K. K. Kelley, *J. Chem. Phys.* 11, 16 (1943) (55-295°K.). This data on integration yielded $S_{298.15}^{\circ} = 6.529$ starting with $S_1^{\circ} = 0.0003$ cal. deg⁻¹ mole⁻¹. The heat capacity and enthalpy data above room temperature are extensive and the heat capacities and enthalpies chosen by R. Hultgren, R. L. Orr, P. D. Anderson and K. K. Kelley, "Selected Values of Thermodynamic Properties of Metals and Alloys" John Wiley and Sons, Inc., New York 1963, were adopted here. These values have a sharp peak in the heat capacity curve at the Curie point* and through this region follow closely the work of P. R. Fallister, *J. Iron Steel Inst.* 167, 87 (1949). This data has recently been corroborated using a pulse heating technique by D. C. Wallace, P. H. Stiles and G. C. Danielson, *J. App. Phys.* 31, 168 (1960). It should be noted that there is some disagreement between the heat capacities chosen and the enthalpies measured by P. D. Anderson and R. Hultgren, *Trans. Met. Soc. AIME*, 224, 842 (1962). The measured values lie consistently above the chosen enthalpies in the range 298-900°K. by from 30 to 60 calories, however the chosen values are considered to be the more reliable. The δ -iron heat capacities adopted here have recently been substantiated confirmed by W. A. Dench and O. Kubashchewski, *J. Iron Steel Inst.* (London) 201, 140 (1963).

Transition Data.

The enthalpies of the α - γ transition at 1184°K. and the δ - γ transition at 1665°K. were also taken from Hultgren et al. loc. cit.

Melting Data.

The temperature and heat of melting were those adopted by Hultgren et al. loc. cit.

Heat of Sublimation.

The value adopted is from a critical second and third law analysis of the data of 14 investigators over gamma-iron and liquid iron. See the Fe(g) table for details.

*See W. P. Giauque, G. E. Brodale, R. A. Fisher and E. W. Hornung, *J. Chem. Phys.* 42, 1 (1965) for the definition of "perit".

IRON (Fe)

(LIQUID)

AT. WT. = 55.85

$$S_{298.15}^{\circ} = 8.195 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1809^{\circ}\text{K.}$$

$$T_b = 3145.4^{\circ}\text{K.}$$

$$\Delta H_f^{\circ} 298.15 = 3.138 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{\circ} = 3.620 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{\circ} = 83.679 \text{ kcal. mole}^{-1}$$

Heat of Formation.

The $\Delta H_f^{\circ} 298.15$ was obtained from that of the crystal by adding ΔH_m and the difference between $H_{1809} - H_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase was that chosen by R. Hultgren, R. L. Orr, P. D. Anderson and K. K. Kelley, "Selected Values of Thermodynamic Properties of Metals and Alloys" John Wiley and Sons, Inc., New York (1963).

Melting Data.

See Fe(c) for details.

Vaporization Data.

The boiling point was calculated from the adopted thermodynamic functions and the chosen heat of sublimation at 298°K. so that the free energy function calculated by integration of the crystal liquid data or by statistical methods from the gas phase were equal at the boiling point.

The adopted value of 99.5 kcal. mole $^{-1}$ is based mainly on the work of Refs. 5, 8 and 14, which have the best drift analysis and agreement between second and third law.

Heat Capacities and Entropies.

The electronic levels were taken from C. E. Moore, Natl. Bur. Standards Circ. 467 (1949). Levels above 20,000 cm $^{-1}$ were averaged.

ΔHf° = Unknown

ΔHf°_{298.15} = -137.2 ± 0.7 kcal/mol

ΔHm° = Unknown

ΔHs°_{298.15} = 58.2 kcal/mol

Heat of Formation.

The heat of combustion of Fe(OH)₂(c), according to the chemical reaction Fe(OH)₂(c) + 1/4 O₂(g) = 1/2 Fe₂O₃(c) + H₂O(l), was determined to be -29.8 ± 0.65 kcal/mol by R. Fricke and S. Rühl, Z. anorg. allgem. chem. 251, 414 (1943). From this data the heat of formation (ΔHf°_{298.15}) was evaluated to be -137.2 ± 0.7 kcal/mol, which was adopted here.

The enthalpy changes for the following three reactions were determined by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882 - 1886:

Reaction	ΔHr° ₂₉₈ , kcal/mol
1. FeCl ₂ (c) = FeCl ₂ (400 H ₂ O)	-17.9
2. FeCl ₂ (200 H ₂ O) + H ₂ SO ₄ (200 H ₂ O) = FeSO ₄ (200 H ₂ O) + 2 HCl(100 H ₂ O)	-3.6
3. FeSO ₄ (aq.) + 2KOH(aq.) = Fe(OH) ₂ (c) + K ₂ SO ₄ (aq.)	-6.34

Using ΔHr°_{298.15} = -81.7 kcal/mol for FeCl₂(c) and those for the other compounds in aqueous solution (assuming aq. = 200 H₂O in Reaction 3) obtained from D.D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," NBS Technical Note 270-1, National Bureau of Standards, 1965, the heat of formation (298.15°K) for Fe(OH)₂(c) was derived as -135.8 kcal/mol which agrees reasonably with the adopted value.

Heat Capacity and Entropy.

The heat capacities, 298.15 - 700°K, and S°_{298.15} were estimated by comparison with those for FeCl₂(c), CaCl₂(c) and Ca(OH)₂(c). The Cp values above 700°K were obtained by graphical extrapolation of the Cp curve plotted using the above Cp values.

Heat of Sublimation.

The value of ΔHs°_{298.15} was calculated as the difference between ΔHf°_{298.15} for Fe(OH)₂(g) and Fe(OH)₂(c).

Heat of Formation.

The equilibrium constants, at temperatures between 1300 and 1460°C, for the chemical reaction $\text{Fe}(c) + 2\text{H}_2\text{O}(g) = \text{Fe}(\text{OH})_2(g) + \text{H}_2(g)$, were determined by G. R. Belton and P. D. Richardson, Trans. Faraday Soc. 58, 1562 (1962). Using these data, the enthalpy change ($\Delta H_{298.15}^\circ$) of the reaction is evaluated to be 35.53 ± 3.0 and 35.57 kcal/mol by the second and third law method, respectively. Based on the third law value for $\Delta H_{298.15}^\circ$, the heat of formation ($\Delta H_{298.15}^\circ$) for $\text{Fe}(\text{OH})_2(g)$ is calculated to be $-79 \pm 0.5 \text{ kcal/mol}$.

Heat Capacity and Entropy.

The molecular structure is assumed to be the same as that for $\text{B}(\text{OH})_2(g)$. The Fe-O bond distance is taken from $\text{FeO}(g)$. The O-H bond distance and Fe-O-H bond angle are estimated from those for $\text{H}_2\text{O}(g)$. The vibrational frequencies, and electronic levels and quantum weights are obtained by comparison with those for $\text{B}(\text{OH})_2(g)$ and $\text{FeCl}_2(g)$, respectively. These values are adjusted to give reasonable second and third law agreements. The three principal moments of inertia are: $I_A = 2.658 \times 10^{-40}$, $I_B = 1.864 \times 10^{-36}$ and $I_C = 1.890 \times 10^{-36} \text{ g cm}^2$.

Heat of Formation.

P. Schindler, W. Michaelis and W. Peitmecht, *Helv. Chim. Acta*, **46**, 444 (1963), investigated the solubility of aged Fe(OH)₃ precipitates by determining the Fe⁺⁺⁺ and H⁺ ion concentration of solution in contact with the solid phase. The ion concentration was measured by the EMF method at the constant ionic strength 3M NaClO₄ (solution). The precipitates were investigated by X-ray and electron microscope methods. The equilibrium constant was derived as log [Fe⁺⁺⁺] [H⁺]⁻³ = log K = 3.55 ± 0.1 for amorphous inactive hydroxide at 25°C. From these data the quantity log K_a = -39.1 ± 0.2 was evaluated where K_a is the solubility product of Fe(OH)₃. The Gibbs energy change (ΔH_f^o_{298.15}) of the reaction Fe(OH)₃(c) = Fe⁺⁺⁺(aq) + 3OH⁻(aq) was calculated to be 53.34 ± 0.27 kcal/mol. Using S_{298.15}^o = 70.1 and -2.57 gibbs/mol for Fe⁺⁺⁺(aq) and OH⁻(aq), respectively, and an estimated S_{298.15}^o(Fe(OH)₃, c) = 25 gibbs/mol, the enthalpy change (ΔH_f^o_{298.15}) of the reaction is calculated to be 22.69 kcal/mol, according to the relationship ΔH = ΔG + TΔS. The entropy values for Fe⁺⁺⁺ and OH⁻ ions were obtained from "Selected Values of Chemical Thermodynamic Properties," Circular 500, National Bureau of Standards, 1952, and NBS Technical Note 270-1 by D. D. Wagman and co-workers, 1965, respectively. Based on ΔH_f^o_{298.15}(Fe⁺⁺⁺, aq) = -11.4 and ΔH_f^o_{298.15}(OH⁻, aq) = -54.97 kcal/mol, taken from the same sources, the heat of formation (ΔH_f^o_{298.15}) for Fe(OH)₃(c) was evaluated to be -199 ± 3 kcal/mol, which was adopted here.

The divergent values for solubility product (SP) of Fe(OH)₃ found in the literature may be due not only to the various forms of precipitate, but also to the tendency to form colloidal solutions. The SP values for Fe(OH)₃ were also reported by Evans and Pryor, *J. Chem. Soc.* **5157** (1949); Kriukor and Aseevetsch, *Z. Elektrochem.* **59**, 884 (1955); Ruff and Hirsch, *Z. Anorg. Chem.* **146**, 338 (1925); Britton, *J. Chem. Soc.* **2148** (1925); and Jellinek and Gordon, *Z. Phys. Chem.* **112**, 207 (1924).

The enthalpy changes (ΔH_f^o_{298.15}) for the reactions: (1) FeCl₃(aq) + 3NaOH(aq) = Fe(OH)₃(c) + 3NaCl(aq) and (2) FeCl₃(c) = FeCl₃(aq) were determined to be -24.50 and -31.66 kcal/mol, respectively, by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882 - 1886. Assuming the aqueous solutions all contain 200 mol of H₂O, the heat of formation (ΔH_f^o_{298.15}) for Fe(OH)₃ was calculated as -196.9 kcal/mol from Reactions (1) and (2). The ΔH_f^o_{298.15} values for NaOH(aq) and NaCl(aq) were obtained from V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NBS-2, National Bureau of Standards, 1965, and JANAP ΔH_f^o_{298.15} values for NaOH(c) and NaCl(c).

Heat Capacity and Entropy.

The heat capacities, S_{298.15} - 1000°K, were estimated by comparison with those for B₂O₃(c), Fe₂O₃(c) and B(OH)₃(c). The Cp values above 1000°K were obtained by graphical extrapolation. The S_{298.15}^o(Fe(OH)₃, c) value was estimated by comparison with that for B(OH)₃(c).

 $\Delta H_f^\circ = \text{Unknown}$ $\Delta H_{298.15}^\circ = -25 \pm 4 \text{ kcal/mol}$ $\Delta H^\circ = 0.2 \text{ kcal/mol}$ $\Delta H_m^\circ = [10.7] \text{ kcal/mol}$ $\Delta H_{298.15}^\circ \text{ (to monomer)} = [46] \text{ kcal/mol}$ $\Delta H_{298.15}^\circ \text{ (to dimer)} = [52] \text{ kcal/mol}$

Heat of Formation.

The chemical equilibrium of the decomposition of $\text{FeI}_2(\text{c})$, $771.15 - 858.15^\circ\text{K}$, has been studied by W. E. Zaugg and N. W. Gregory, *J. Phys. Chem.* **70**, 486 (1966). Using the reported partial pressures for $\text{I}_2(\text{g})$, the enthalpy change ($\Delta H_{298.15}^\circ$) for the reaction $\text{FeI}_2(\text{c}) = \text{Fe}(\text{c}) + \text{I}_2(\text{g})$ was evaluated by both the second and third law methods to be 39.79 ± 1.0 and $39.69 \pm 0.3 \text{ kcal/mol}$, respectively. Based on the third law $\Delta H_{298.15}^\circ$ value, the heat of formation ($\Delta H_{298.15}^\circ$) for $\text{FeI}_2(\text{c})$ was calculated as -25 kcal/mol which was adopted here.

The enthalpy change for the reaction $\text{FeI}_2(\text{c}) = \text{Fe}^{++}(\text{aq}) + 2 \text{I}^-(\text{aq})$ was determined to be $-19.48 \pm 0.03 \text{ kcal/mol}$ by P. Paoletti, A. Sabatini and A. Vacca, *Trans. Faraday Soc.* **61**, 2417 (1965), using a solution calorimetric method. Adopting $\Delta H_{298.15}^\circ = -21.3$ and -13.9 kcal/mol for $\text{Fe}^{++}(\text{aq})$ and $\text{I}^-(\text{aq})$, respectively, the value of $\Delta H_{298.15}^\circ$ (FeI_2, c) was derived as $-28.22 \pm 1 \text{ kcal/mol}$. The value of $\Delta H_{298.15}^\circ (\text{I}^-, \text{aq})$ was taken from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey, and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Part 1, Technical Note 270-1, National Bureau of Standards, 1955. The value of $\Delta H_{298.15}^\circ (\text{Fe}^{++}, \text{aq})$ was derived from heats of solution and formation for $\text{FeCl}_2(\text{c})$.

The heats of solution of $\text{Fe}(\text{c})$, $\text{I}_2(\text{c})$ and $\text{FeI}_2(\text{c})$ in aqueous $\text{Br}_2\text{-KBr}$ solution were measured by W. Hieber and A. Moerner, *Z. Elektrochem.* **40**, 287 (1934), using an ice calorimeter. From the results obtained the heat of formation for $\text{FeI}_2(\text{c})$ was reported as -30.1 kcal/mol .

Heat Capacity and Entropy.

The heat capacities, $343.15 - 773.15^\circ\text{K}$, were measured by P. L. Oetting and N. W. Gregory, *J. Phys. Chem.* **65**, 173 (1961). The C_p values at temperatures below 343.15 and above 773.15°K were estimated by graphical extrapolation. The low temperature heat capacities, $11-130^\circ\text{K}$, were determined by O. Miljutin and E. A. Parfenova, *Phys. Trans. Ukrain, Acad. Sci.* **5**, 81 (1940). These data appear to be inadequate for the derivation of the entropy at 298.15°K . The value of $S_{298.15}$ adopted was calculated from the entropy change, $\Delta S_{298.15}^\circ = 28.7 \text{ eu}$, for the decomposition reaction $\text{FeI}_2(\text{c}) = \text{Fe}(\text{c}) + \text{I}_2(\text{g})$, obtained by the second law analysis of the equilibrium pressure data reported by W. E. Zaugg and N. W. Gregory, *J. Phys. Chem.* **70**, 486 (1966).

Transition Data.

A minor transition in the vicinity of 370°C ($360-385^\circ\text{C}$) has been reported by P. L. Oetting and N. W. Gregory, *loc. cit.* Subsequent studies by T. J. Wydeven, Ph. D. Thesis, University of Washington, Seattle, Wash., 1964, have shown the magnitude of the transition to be sensitive to trace amounts of impurities, but the nature of the transition has not been clearly established. A magnetic transition at 10°K was reported by H. Bizotte, C. Terrier and E. Tsal, *Compt. rend.* **245**, 507 (1957). The ΔH° value was evaluated from the heat capacity - temperature plot given by P. L. Oetting and N. W. Gregory, *loc. cit.*

Melting Data.

T_m was reported by W. Fischer and R. Gwehn, *Z. anorg. allgem. Chem.* **222**, 303 (1935). ΔH_m° was estimated by comparison with that for $\text{FeBr}_2(\text{c})$.

Heat of Sublimation.

$\Delta H_{298.15}^\circ$ (to monomer) is calculated as the difference between $\Delta H_{298.15}^\circ$ for $\text{FeI}_2(\text{g})$ and $\text{FeI}_2(\text{c})$. $\Delta H_{298.15}^\circ$ (to dimer) was calculated as the difference between those for $\text{Fe}_2\text{I}_4(\text{g})$ and $2 \text{FeI}_2(\text{c})$.

ΔH°_{298.15} = [16.966] kcal/mol

ΔH° = [10.7] kcal/mol

ΔH° = [25.0] kcal/mol

S°_{298.15} = [46.720] gibbs/mol

T_m = 860 ± 2° K

T_b = [1366] °K

Heat of Formation.

The heat of formation (ΔH°_{298.15}) was obtained from ΔH°_{298.15} (c) by adding ΔH° and the difference between H° - H°_{298.15} for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was assumed to be constant in the temperature range from 298.15 to 2000°K. The value of Cp was calculated on an assumption that Cp = 9.0 gibbs/g-atom for FeI₂(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Vaporization Data.

T_b is the temperature at which the vapor pressure of FeI₂(g) and Fe₂I₄(g) over FeI₂(l) equals one atmosphere. The value of ΔH° is derived from the vapor composition and the heats of vaporization of FeI₂(l) to monomer and dimer at T_b.

Heat of Formation

The chemical equilibria for the reactions: (A) FeI₂(g) = FeI₂(g), (B) FeI₂(1) = FeI₂(g), and (C) Fe(c) + 2I(g) = FeI₂(g), have been studied by several investigators. Based on the equilibrium pressures reported, the corresponding enthalpy changes were evaluated by both the second and third law methods. The results obtained are presented in the table below. Using the third law ΔH_{298.15} values, the heats of formation for FeI₂(g) were calculated. The adopted value for ΔH_{298.15}(FeI₂, g) is 21.0 ± 3 kcal/mol. The disagreement between the acts of second and third law ΔH_{298.15} values listed in the table may be due to the presence of dimer, Fe₂I₄(g), which was not accounted for in deriving the partial pressure of FeI₂(g). The data obtained from Schoonmaker et al. was adjusted for the presence of dimer.

Investigator	Reaction	Temperature, °K	Method	Second Law Value	Third Law Value	Drift kcal/mol
Schäfer and Hones ¹	(A)	790.15 - 850.15	Transpiration	41.61	46.58	+ 5.78

¹The vapor pressure data used for evaluation were those adjusted by V. E. Zaugg and N. W. Gregory, J. Phys. Chem. **70**, 490 (1966).

²H. Schäfer and W. J. Hones, Z. Anorg. Allgem. Chem. **286**, 82 (1956).

³R. C. Schoonmaker, A. H. Friedman and P. R. Porter, J. Chem. Phys. **31**, 1586 (1959).

⁴R. J. Sine and N. W. Gregory, J. Phys. Chem. **64**, 86 (1960). The vapor pressure equation used for calculation is log P_{mm} = -(9760/T) + 11.82. In the original paper, the term A = 960 should be 9760.

⁵W. E. Zaugg and N. W. Gregory, J. Phys. Chem. **70**, 490 (1966).

Heat Capacity and Entropy

The molecular structure was assumed to be linear. The Fe-I bond distance was estimated by L. Brewer, G. R. Somayajulu and E. Brackett, Chem. Rev. **53**, 111 (1963). The vibrational frequencies were estimated so that the derived Gibbs energy functions yielded second and third law ΔH_{298.15} values in reasonable agreement (see the above table). The electronic levels and quantum weights were estimated from those for FeI₂(g) reported by C. W. DeKock and D. M. Gruen, J. Chem. Phys. **44**, 4387 (1966). The moment of inertia is 2.4884 x 10⁻³⁷ g cm².

$$\Delta H_f^0 = -63.65 \pm 0.20 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 \text{ 298.15} = -63.64 \pm 0.20 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = 7.49 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 13.764 \pm 0.10 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1650^\circ\text{K.}$$

Heat of Formation.

The chemical equilibria in the Fe-C-O and Fe-H-O systems have been studied by many investigators. Using the reported equilibrium constants for the following two reactions (1) $\text{Fe}_0.947\text{O}(c) + \text{CO}(g) = 0.947\text{Fe}(c) + \text{CO}_2(g)$ and (2) $\text{Fe}_0.947\text{O}(c,1) + \text{H}_2(g) = 0.947\text{Fe}(c) + \text{H}_2\text{O}(g)$, the corresponding enthalpy changes (ΔH_f^0) were evaluated by both the second and third law methods. Based on the third law values for ΔH_f^0 , the ΔH_f^0 298.15 (Wüstite, c) values were also calculated. The results obtained are presented as follows.

Investigator	Reaction	Temperature, °K.	Second Law Value	Third Law Value	ΔH_f^0 298.15 kcal. mole ⁻¹
Eastman ¹	(1)	873.2-1273.2	-3.80 ± 0.01	-4.01	-63.63

Britzke et al. ⁴	(3)	1698.0-1700.0	—	0.87	-62.72
		1123.0-1473.0	-129.08 ± 0.18	-126.28	-65.14

¹ E. D. Eastman, *J. Am. Chem. Soc.* **44**, 975 (1922).

² E. D. Eastman and R. M. Evans, *J. Am. Chem. Soc.* **46**, 888 (1924). The K_p value at 1273.2°K. for reaction (1) is rejected by a statistical criterion.

³ P. H. Emmett and J. F. Schultz, *J. Am. Chem. Soc.* **52**, 4268 (1930).

⁴ E. V. Britzke, A. F. Kapustinsky and N. I. Schastkina, *Z. anorg. allgem. Chem.* **219**, 287 (1934). The K_p value at 1123°K. for reaction (3) is rejected by a statistical criterion.

⁵ W. E. Joninry and D. W. Murphy, *Ind. Eng. Chem.* **23**, 384 (1931). The K_p values at 1530 and 1645°K. are rejected by a statistical criterion.

⁶ J. Chipman and S. Marshall, *J. Am. Chem. Soc.* **62**, 299 (1940).

Britzke et al. also determined the equilibrium pressures for the reaction (3) $1.894 \text{ Fe}(c) + \text{O}_2(g) = 2\text{Fe}_0.947 \text{O}(c)$. The corresponding ΔH_f^0 298.15 for Wüstite was evaluated based on the third law value for ΔH_f^0 298.15. The adopted value of ΔH_f^0 298.15 (Wüstite, c) is the weighted average of the ΔH_f^0 298.15 listed in the above table.

Heat Capacity and Entropy.

The low temperature (54.37-298.16°K.) heat capacities (C_p) were measured by S. S. Todd and K. R. Bonnickson, *J. Am. Chem. Soc.* **73**, 3894 (1951). The high temperature (298-1650°K.) heat capacities were determined by J. P. Coughlin, E. G. King and K. R. Bonnickson, *J. Am. Chem. Soc.* **73**, 3891 (1951). The two sets of C_p data were plotted and joined smoothly at 298°K. The C_p values above 1650°K. were obtained by graphical extrapolation. The low temperature (70.7-279.8°K.) C_p 's were also reported by R. W. Millar, *J. Am. Chem. Soc.* **51**, 215 (1929). $S_{298.15}^0$ was derived from the low temperature heat capacities, based on $S_{52}^0 = 0.696 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$, S. S. Todd and K. R. Bonnickson, loc. cit. added 0.41 e.u., the amount calculated for completely random distribution of the vacant Fe spaces in the Wüstite lattice. However, the free energy functions derived from $S_{52}^0 = 0.696 \text{ e.u.}$ give better agreement between second and third law values for ΔH_f^0 than those derived from $S_{52}^0 = 1.11 \text{ e.u.}$ Therefore the value 0.41 e.u. was not added here.

Melting Data.

T_m and ΔH_m^0 were taken from J. P. Coughlin, E. G. King and K. R. Bonnickson, et al. T_m was reported as 1372°C. (1645°K.) by L. S. Darken and R. W. Durr, *J. Am. Chem. Soc.* **68**, 798 (1946) and as 1569°C. (1642°K.) by J. Chipman and S. Marshall, loc. cit.

FeO

$S_{298.15}^o = [14.52] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o = \text{Unknown}$
 $\Delta H_f^o 298.15 = [-65.02] \text{ kcal. mole}^{-1}$
 $\Delta H_m^o = [5.75] \text{ kcal. mole}^{-1}$
 $\Delta H_g^o 298.15 = [121.62] \text{ kcal. mole}^{-1}$
 $T_m = [1650]^{\circ}\text{K.}$

Heat of Formation.

The value of $\Delta H_f^o 298.15$ for FeO(c) was derived based on an assumption that at 1650°K., $\Delta H_f^o(\text{FeO, c}) = \Delta H_f^o(\text{FeO, l})$. From the value $\Delta H_f^o 1650(\text{FeO, c}) = -59.77 \text{ kcal. mole}^{-1}$, $\Delta H_f^o 1650(\text{FeO, c})$ was calculated to be $-63.97 \text{ kcal. mole}^{-1}$, yielding $\Delta H_f^o 298.15(\text{FeO, c}) = -65.02 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The C_p values were estimated assuming $C_p(\text{FeO, c}) = C_p(\text{Wüstite, c}) + 0.053 C_p(\text{Fe, c})$. The C_p values obtained were plotted. The adopted C_p points were taken from the smoothed C_p curve. $S_{298.15}^o$ for FeO(c) was calculated as $S^o(\text{FeO, c}) = S^o(\text{Wüstite, c}) + 0.053 S^o(\text{Fe, c}) + \Delta S^o(\text{mixing})$ where ΔS^o is the entropy of mixing (0.41 cal. deg.⁻¹ mole⁻¹).

Melting Data.

T_m is assumed to be the same as that for Wüstite. The difference between $\Delta H_f^o 1650$ for FeO(l) and FeO(c) is ΔH_m^o .

Heat of Sublimation.

$\Delta H_g^o 298.15$ is calculated as the difference between $\Delta H_f^o 298.15$ for FeO(g) and FeO(c).

$S_{298.15}^{\circ} = 18.029$ cal. deg⁻¹ mole⁻¹
 $T_m = [1650]^{\circ}\text{K}$.
 $T_d = [3687]^{\circ}\text{K}$.

Heat of Formation.
 $\Delta H_f^{\circ} 298.15 = [-59.642]$ kcal. mole⁻¹
 $\Delta H_m^{\circ} = [5.75]$ kcal. mole⁻¹

The heat of formation ($\Delta H_f^{\circ} 298.15$) was evaluated based on an assumption that the heat of melting of wüstite, $\Delta H_m^{\circ} = 7.49$ kcal. mole⁻¹, represents the enthalpy change of the reaction $\text{FeO}_{0.947}(\text{c}) = 0.947 \text{FeO}(\text{l}) + \frac{0.053}{2} \text{O}_2(\text{g})$. In other words, during melting the wüstite releases $\text{O}_2(\text{g})$ and converts to $\text{FeO}(\text{l})$.

Heat Capacity and Entropy.

The enthalpy changes ($H_f^{\circ} - H_{298.15}^{\circ}$) of liquid iron oxide were determined by J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3591 (1951). The C_p (FeO , l) was derived as 16.3 cal. deg⁻¹ mole⁻¹. This value was adopted as the heat capacity for $\text{FeO}(\text{l})$ up to 4000°K. A glass transition temperature was assumed at 1100°K. $S_{298.15}^{\circ}$ (FeO , l) was calculated based on an assumption that the entropy of melting of wüstite represents also the entropy change of the reaction, $\text{FeO}_{0.947}(\text{c}) = 0.947 \text{FeO}(\text{l}) + \frac{0.053}{2} \text{O}_2(\text{g})$. From the entropy of melting, $\Delta S_m^{\circ} 1650 = 4.539$ e.u., the value $S_{298.15}^{\circ}$ (FeO , l) = 18.029 e.u. was derived.

Melting Data.

The melting point (T_m) for wüstite ($\text{FeO}_{0.947}$, c) has been reported by many investigators. However, the composition of the liquid state of wüstite was not identified. An assumption was made that during melting the reaction $\text{FeO}_{0.947}(\text{c}) = 0.947 \text{FeO}(\text{l}) + \frac{0.053}{2} \text{O}_2(\text{g})$ occurs. Hence the related thermodynamic properties were derived.

Decomposition Temperature.

T_d is the temperature at which ΔF_f° equals zero.

IRON OXIDE (FeO)

 $\sigma = 1$ $\omega_e = 880.0 \text{ cm}^{-1}$
 $\omega_e x_e = [0.00293] \text{ cm}^{-1}$
 $\tau_e = [1.8] \text{ \AA}$

Heat of Formation

The heat of formation for FeO(g) is not well established at the present time. The values of ΔH_f° (FeO, g) derived from the following reactions: (1) FeO(g) = Fe(g) + O(g), (2) FeO(g) = Fe(g) + 1/2 O₂(g), and (3) FeO(l) = FeO(g), are not in agreement. There are three D^o (Fe-O) values reported for reaction (1). The enthalpy change for reaction (2) was evaluated based on the partial pressure data ($P_{\text{FeO}}/P_{\text{Fe}} = 0.2$ at 1600°C, measured by Washburn⁴, using a mass spectrometric method, U. S. Atomic Energy Commission, UCRL-10991, August 1963, and $P_{\text{O}_2} = 1.66 \times 10^{-6}$ atm reported by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 68, 796 (1946). The enthalpy value for reaction (3) was calculated based on the reported value, $\Delta H_f^\circ = 96.096 \text{ kcal/mol}$ determined by Burtsev, Karasev and Samarin⁵. The results obtained are presented as follows. The value of ΔH_f° for FeO(g) adopted is $80 \pm 5 \text{ kcal/mol}$.

3. A. Lagerqvist and L. Huldt, Z. Naturforsch. 8d, 483 (1953). D^o was derived from atomic spectra of Fe produced by acetylene-air flame method.

4. J. Washburn, UCRL 10991, August 1963, obtained from L. Brewer, private communication, October 18, 1966.

5. V. T. Burtsev, R. A. Karasev and A. M. Samarin, Fiz.-Khim. Osnovy Proizv. Stal', Akad. Nauk SSSR, Inst. Met., Tr. 5-01 (Shestol) Konf., Moscow, 366 (1961); published in 1964.

Heat Capacity and Entropy

Since the ground state configuration is due to Fe⁺⁺ in a ligand field, it was assumed to be the same as that of FeCl₂(g) reported by C. W. Decock and D. M. Gruen, J. Chem. Phys. 44, 4387 (1966). The electronic levels and quantum weights were estimated by comparison with those of FeCl₂(g). The values of ω_e and $\omega_e x_e$ were taken from G. Herzberg, loc. cit. The bond distance was calculated according to the method suggested by K. M. Osgood, Proc. Phys. Soc. (London) 86, 456 (1966), assuming FeO(g) as a polar molecule. The value of B_e was calculated by use of the relationship: $B_e = (2.79976 \times 10^{-39}) / I$ where I is the moment of inertia of FeO(g). The value of α_e was derived from ω_e , $\omega_e x_e$ and B_e by the method suggested by G. Herzberg, loc. cit. The principal moment of inertia is $6.6899 \times 10^{-39} \text{ g cm}^2$.

$\Delta H^\circ_0 = -219.7 \pm 2 \text{ kcal/mol}$
 $\Delta H^\circ_{298.15} = -222.0 \pm 2 \text{ kcal/mol}$
 $S^\circ_{298.15} = 28.91 \pm 0.3 \text{ gibbs/mol}$
 $T_d = 944^\circ\text{K}$

Heat of Formation.

The enthalpy change for the reaction $\text{FeSO}_4(c) = \text{FeSO}_4(110 \text{ H}_2\text{O})$ was determined to be -14.9 kcal/mol by R. de Forcrand, Comp. rend. 158, 20 (1914). Using $\Delta H^\circ_{298.85} = -235.85 \text{ kcal/mol}$ for $\text{FeSO}_4(110 \text{ H}_2\text{O})$, the heat of formation (298.15°K) for $\text{FeSO}_4(c)$ was calculated as -221 kcal/mol . The value of $\Delta H^\circ_{298.15}(\text{FeSO}_4, c)$ was estimated based on $\Delta H^\circ_{298.15} = 235.9 \text{ kcal/mol}$ for $\text{FeSO}_4(200 \text{ H}_2\text{O})$ and $2\text{HCl}(100 \text{ H}_2\text{O})$ which was derived from the enthalpy change for the reaction $\text{FeCl}_2(200 \text{ H}_2\text{O}) + \text{H}_2\text{SO}_4(200 \text{ H}_2\text{O}) = \text{FeSO}_4(200 \text{ H}_2\text{O}) + 2\text{HCl}(100 \text{ H}_2\text{O})$ measured by J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882-1886. See the $\text{Fe}(\text{OH})_2(c)$ table for details.

The decomposition pressures of $\text{FeSO}_4(c)$ at different temperatures were investigated by J. D'Ans and E. Greulich. Using their reported partial pressures for $\text{SO}_3(g)$ and $\text{SO}_2(g)$, the enthalpy change for the reaction $2 \text{FeSO}_4(c) = \text{Fe}_2\text{O}_3(c) + \text{SO}_3(g) + \text{SO}_2(g)$ was evaluated by both the second and third law methods. The results obtained are presented in the following table.

Investigator	Temperature, °K	Second Law Value	Third Law Value	$\Delta H^\circ_{298.15}$ kcal/mol
1. J. D'Ans (1905)	753.15 - 908.15	83.2 ± 4.6	82.7 ± 1.1	-222.7
2. E. Greulich (1927)	887.15 - 971.15	84.8 ± 8.8	80.1 ± 1.4	-221.5
3. B. Neumann and G. Heintke (1937)	835.15 - 862.15	72.4 ± 5.4	75.3 ± 0.5	-219.1

1. J. D'Ans, Dissertation, Darmstadt, 1905. Data quoted by B. Neumann and G. Heintke, loc. cit.
2. E. Greulich, Z. anorg. Chem. 169, 197 (1927). Only the last seven high temperature points were adopted for evaluation.
3. B. Neumann and G. Heintke, Z. Elektrochem. 43, 246 (1937), based on the last 18 high temperature points adopted.

The decomposition pressures assumed for the same reaction have been determined by B. Neumann and G. Heintke. From their data the partial pressures for $\text{SO}_3(g)$ and $\text{SO}_2(g)$ were evaluated. Using the derived $\text{SO}_3(g)$ and $\text{SO}_2(g)$ partial pressures, the corresponding enthalpy changes for the reaction were calculated by both the second and third law methods. The results obtained are also listed in the same table.

The value of $\Delta H^\circ_{298.15}$ for $\text{FeSO}_4(c)$ is selected as $-222 \pm 2 \text{ kcal/mol}$.

Heat Capacity and Entropy.

The low temperature heat capacities, $53.0-294.9^\circ\text{K}$, were determined by O. E. Moore and K. K. Kelley, J. Am. Chem. Soc., 64, 2949 (1942). Based on $S^\circ_{50.12} = 2.10 \text{ eu}$, the value of $S^\circ_{298.15}(\text{FeSO}_4, c)$ was reported to be $25.71 \pm 0.2 \text{ eu}$. Using the free energy functions for $\text{FeSO}_4(c)$ based on this $S^\circ_{298.15}$ value, to evaluate the vapor pressure data for Reaction (1), the second and third law values of $\Delta H^\circ_{298.15}$ were derived as 72.36 ± 7.60 and $86.51 \pm 1.26 \text{ kcal/mol}$, respectively. Since the report by Moore and Kelley, loc. cit., did not mention the magnetic entropy contribution, an attempt was made to add $3.20 (= R \ln 5)$ eu to $S^\circ_{298.15}(\text{FeSO}_4, c)$ and re-evaluate the decomposition pressure data. The results obtained were better than before (see the paragraph on "Heat of Formation," for details). Therefore the value, $S^\circ_{298.15} = 25.71 + 3.2 = 28.91 \text{ eu}$ for $\text{FeSO}_4(c)$, was adopted. The heat capacities above 294.9°K were estimated by comparison with those for $\text{MnSO}_4(c)$. The high temperature heat capacities, $870.3-1082.3^\circ\text{K}$, were determined by J. C. Southard and C. H. Shomate, J. Am. Chem. Soc. 64, 1770 (1942). The two sets of data were joined smoothly at 298.15°K by use of Shomate-function plot.

Temperature of Decomposition.

T_d is the temperature at which the vapor pressure of the gaseous decomposition products equals one atmosphere, which was obtained by graphical interpolation of the decomposition pressure data on $\text{FeSO}_4(c)$, reported by E. Greulich, loc. cit.

Heat of Formation.

The chemical equilibrium of the interaction of Fe(c) and I(g) has been studied by a transpiration method by W. E. Zaugg and N. W. Gregory, J. Phys. Chem. **70**, 490 (1966). Using the reported equilibrium constants in the temperature range from 591 to 751°K, the enthalpy change ($\Delta H_{298.15}^\circ$) of the reaction $2\text{Fe}(c) + 4 \text{I}(g) = \text{Fe}_2\text{I}_4(g)$ was evaluated by both the second and third law method to be -85.3 and -103.75 kcal/mol, respectively. The corresponding values of the heat of formation ($\Delta H_{298.15}^\circ$) for $\text{Fe}_2\text{I}_4(g)$ were calculated as +16.9 and -1.6 kcal/mol.

Mass spectrometric and Knudsen effusion techniques have been used to study the vaporization of $\text{FeI}_2(c)$ by R. C. Schoonmaker, A. H. Friedman and R. P. Porter, J. Chem. Phys. **31**, 1988 (1959). Using the reported vapor pressure, $P = 1.21 \times 10^{-6}$ atm. at 714°K for $\text{Fe}_2\text{I}_4(g)$, the enthalpy change ($\Delta H_{298.15}^\circ$) for the reaction $2 \text{FeI}_2(c) = \text{Fe}_2\text{I}_4(g)$ was evaluated by the third law method as 52.8 kcal/mol, yielding $\Delta H_{298.15}^\circ = 2.8$ kcal/mol for $\text{Fe}_2\text{I}_4(g)$.

The adopted value of $\Delta H_{298.15}^\circ$ for $\text{Fe}_2\text{I}_4(g)$ is 2.0 ± 5 kcal/mol.

Heat Capacity and Entropy.

The molecular structure was assumed to be the same as that assumed for $\text{Fe}_2\text{Br}_4(g)$. The Fe-I bond distance was estimated from that in $\text{FeI}_2(g)$ molecule. Four vibrational frequencies (ν_i), i.e. 1 = 2, 4, 5 and 6, were estimated by comparison with those for $\text{K}_2\text{I}_2(g)$, calculated by J. Berkowitz, J. Chem. Phys. **32**, 1519 (1960). The other frequency values were estimated from those for $\text{FeI}_2(g)$. The electronic levels and quantum weights were estimated from those for $\text{FeI}_2(g)$. The three principal moments of inertia are: $I_A = 1.2442 \times 10^{-57}$, $I_B = 7.7996 \times 10^{-57}$ and $I_C = 9.0439 \times 10^{-57} \text{ g cm}^2$.

HEMATITE (Fe₂O₃) (CRYSTAL)Fe₂O₃

MOL. WT. = 159.6922

$$\Delta H_f^{\circ} 0 = -195.8 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^{\circ} 298.15 = -197.3 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$S^{\circ} 298.15 = 20.889 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_d = 1755^{\circ}\text{K.}$$

Heat of Formation.

The chemical equilibria for the reaction $4\text{Fe}_2\text{O}_3(\text{c}) + \text{O}_2(\text{g}) = 6\text{Fe}_2\text{O}_3(\text{c})$ have been studied by several investigators. From the reported data the corresponding values of $\Delta H_f^{\circ} 298.15$ and $\Delta H_f^{\circ} 298.15$ (Fe_2O_3 , c) were evaluated. The results obtained are given as follows.

Investigator	Temperature, °K.	Second Law Value	Third Law Value	$\Delta H_f^{\circ} 298.15^{\circ}$ kcal. mole ⁻¹
Tretyskov and Khomyakov ¹	1373-1728	-106.32 ± 0.19	-111.05	-197.11
Schmahl ²	1583-1683	-123.95 ± 1.37	-112.94	-197.42
Smitten ³	1373-1673	-117.68 ± 0.38	-114.25	-197.64
Darkey and Gurry ⁴	1725	-110.29	—	-196.98

*Calculation based on the third law values for $\Delta H_f^{\circ} 298.15$.

1 Y.D. Tretyskov and K. G. Khomyakov, Russ. J. Inorg. Chem. **7**, 628 (1962).

2 N. G. Schmahl, Z. Elektrochem. **47**, 821 (1941).

3 J. Smitten, J. Am. Chem. Soc. **79**, 4877 (1957).

4 L. S. Darkey and R. W. Gurry, J. Am. Chem. Soc. **68**, 799 (1946). $\Delta H_f^{\circ} 298.15$ was calculated based on $\Delta H_f^{\circ} 1725 = -54.5 \text{ kcal. mole}^{-1}$.

The value of $\Delta H_f^{\circ} 298.15$ adopted for $\text{Fe}_2\text{O}_3(\text{c})$ is the weighted average of the $\Delta H_f^{\circ} 298.15$ values listed in the above table.

Heat Capacity and Entropy.

The low temperature (5.58-345.42°K.) heat capacities were determined by P. Gronvold and E. P. Westrum, Jr., J. Am. Chem. Soc. **81**, 1780 (1959). The high temperature (298-1750°K.) C_p values were obtained from J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. **73**, 3891 (1951). The two sets of data were plotted and joined smoothly at 298°K. The C_p values above 1750°K. were obtained by graphical extrapolation. The heat capacities of $\text{Fe}_2\text{O}_3(\text{c})$ have also been reported by G. G. Brown and C. C. Furnas, Trans. Am. Inst. Chem. Eng. **18**, 309 (1926), 0-650°K., and G. S. Parks and K. K. Kelley, J. Phys. Chem. **50**, 47 (1946), 96-289°K. $S^{\circ} 298.15$ for $\text{Fe}_2\text{O}_3(\text{c})$ was derived from the smoothed C_p data, based on $S^{\circ} = 0.0003 \text{ e.u.}$ J. P. Coughlin, E. G. King and K. R. Bonnickson, loc. cit. measured the heat-content for hematite and found two anomalies, presumably of magnetic nature, at about 950 and 1050°K., respectively. Both appear to involve maxima in the heat-capacity curves rather than isothermal heats of transformation. The complex magnetic properties at low temperatures were discussed by P. Gronvold and E. P. Westrum, Jr., loc. cit. No heat capacity anomaly was observed at the magnetic transition about 250°K. The Curie points of the antiferromagnetic $\alpha\text{-Fe}_2\text{O}_3$ were reported by A. Aharoni, E. H. Frei and M. Schieber, Phys. Rev. **127**, 439 (1962) and J. Lieke and A. C. D. Chakrader, Phys. Rev. Letters, **13**, 866 (1965).

Temperature of Decomposition.

T_d is the temperature at which $\Delta H_f^{\circ} = 0$ for the reaction $6\text{Fe}_2\text{O}_3(\text{c}) = 4\text{Fe}_3\text{O}_4(\text{c}) + \text{O}_2(\text{g})$. In other words, $\text{Fe}_2\text{O}_3(\text{c})$ decomposes into $\text{Fe}_3\text{O}_4(\text{c})$ and $\text{O}_2(\text{g})$ at 1755°K.

$S_{298.15}^\circ = [73.5 \pm 2] \text{ gibbs/mol}$
 $T_D = 1451^\circ\text{K}$
 $\Delta H_{298.15}^\circ = -617.35 \pm 0.40 \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = \text{Unknown}$

Heat of Formation.

The enthalpy change ($\Delta H_{298.15}^\circ$) for the chemical reaction $\text{Fe}_2\text{O}_3(\text{c}) + 3\text{H}_2\text{SO}_4(14.855 \text{ H}_2\text{O}) = \text{Fe}_2(\text{SO}_4)_3(\text{c}) + 3\text{H}_2\text{O}(1)$ was measured to be $8.54 \pm 0.18 \text{ kcal/mol}$ by solution calorimetry by R. Barany and L. H. Jermol, U. S. Bur. Mines RI 6687, 1965. Using $\Delta H_{298.15}^\circ = -211.178 \text{ kcal/mol}$ for $\text{H}_2\text{SO}_4(14.855 \text{ H}_2\text{O})$ and -68.315 kcal/mol for $\text{H}_2\text{O}(1)$, obtained from "Selected Values of Chemical Thermodynamic Properties," NBS Technical Note 270-1, by D. D. Wagman and coworkers, National Bureau of Standards, 1965, and -197.3 kcal/mol for $\text{Fe}_2\text{O}_3(\text{c})$, the heat of formation ($\Delta H_{298.15}^\circ$) for $\text{Fe}_2(\text{SO}_4)_3(\text{c})$ was evaluated as $-617.35 \pm 0.40 \text{ kcal/mol}$ which was adopted here.

The equilibrium pressures for the decomposition of $\text{Fe}_2(\text{SO}_4)_3(\text{c})$ have been determined by several investigators at different temperatures. The chemical reactions involved are: (1) $\text{Fe}_2(\text{SO}_4)_3(\text{c}) = \text{Fe}_2\text{O}_3(\text{c}) + 3\text{SO}_3(\text{g})$ and (2) $\text{SO}_3(\text{g}) = \text{SO}_2(\text{g}) + 0.5 \text{ O}_2(\text{g})$. However, the measured pressure of the chemical equilibrium is the total pressure of three partial pressures, namely, P_{SO_3} , P_{SO_2} , and P_{O_2} . In order to calculate the enthalpy change of Reaction (1), the partial pressures of $\text{SO}_3(\text{g})$ were evaluated from the total vapor pressure data at each temperature. Based on the derived values for P_{SO_3} , the $\Delta H_{298.15}^\circ$ value for Reaction (1) was calculated by both the second and third law methods. The results obtained are presented in the following table. The $\Delta H_{298.15}^\circ$ ($\text{Fe}_2(\text{SO}_4)_3$, c) values were derived, using the third law $\Delta H_{298.15}^\circ$. These determinations were not given any weight.

Investigator	Temperature, °K	Second Law Value	Third Law Value	Drift	$\Delta H_{298.15}^\circ$, kcal/mol

6. N. A. Warner and T. R. Ingraham, Can. J. Chem. 38, 2196 (1960).

The decomposition pressures of $\text{Fe}_2(\text{SO}_4)_3(\text{c})$ have also been investigated by M. Grunzweig, Ph. D. dissertation, Darmstadt, Germany, 1913, 793-994 K; R. F. Blanks, Ph. D. dissertation, University of Melbourne, Australia, 1961, 845 - 976° K; and T. R. Ingraham, Internal Rept. EMT-63-17, Department of Mines and Technical Surveys, Ottawa, Canada, 1963, 856-995°K. These data together with some of the data mentioned previously were critically reviewed by H. H. Kellogg, Trans. AIME, 230, 1622 (1964).

Heat Capacity and Entropy.

The heat capacities were estimated by comparison with those for $\text{FeSO}_4(\text{c})$, assuming their average specific heats, gibbs/g, to be the same. The value of $S_{298.15}^\circ$ was estimated so that the second and third law $\Delta H_{298.15}^\circ$ values, derived from decomposition pressure data, are in reasonable agreement.

Temperature of Decomposition.

T_D is the temperature at which the total pressure of the gaseous products equals one atmosphere, which was obtained by graphical extrapolation of the decomposition pressure data measured by Warner and Ingraham, loc. cit.

Heat of Formation.

The equilibrium constants for the following four reactions, i.e. (1) $3\text{Fe}(c) + 4\text{H}_2\text{O}(g) = \text{Fe}_3\text{O}_4(c) + 4\text{H}_2(g)$; (2) $\text{Fe}_3\text{O}_4(c) + \text{H}_2(g) = 3\text{FeO}(c) + \text{CO}_2(g)$; and (4) $2\text{Fe}_3\text{O}_4(c) = 6\text{FeO}(c) + \text{O}_2(g)$, have been studied by several investigators. Using their reported equilibrium data, the corresponding enthalpy changes ($\Delta H_f^{298.15}$) were evaluated by both the second and third law methods. Based on the third law value for $\Delta H_f^{298.15}$, the respective $\Delta H_f^{298.15}$ values for $\text{Fe}_3\text{O}_4(c)$ were also derived. The results obtained are presented as follows.

Investigator	Reaction	Temperature, °K.	Second Law Value	Third Law Value	$\Delta H_f^{298.15}$ kcal. mole ⁻¹

1 R. Prickett, K. Walter and W. Lehnert, Z. Elektrochem. 47, 487 (1941). The two $\Delta H_f^{298.15}$ values listed are the average values of three separate results derived from three sets of experimental data.

2 E. D. Eastman, J. Am. Chem. Soc. 44, 975 (1922).

3 E. D. Eastman and R. M. Evans, J. Am. Chem. Soc. 46, 888 (1924).

4 P. H. Emmett and J. P. Schultz, J. Am. Chem. Soc. 52, 4268 (1930).

5 O. N. Salmon, J. Phys. Chem. 65, 550 (1961).

The enthalpy change of the reaction $\text{Fe}_3\text{O}_4(c) + 0.8215 \text{Fe}(c) + 0.5787 \text{O}_2(g) = 0.5895 \text{Fe}_3\text{O}_4(c)$ has been determined by O. L. Humphrey, E. G. King and K. K. Kelley, U. S. Bur. Mines RI 4870 (1952). Based on $\Delta H_f^{298.15} = -93.46$ kcal. mole⁻¹ (average of two separate values derived from two experimental determinations) and $\Delta H_f^{298.15}$ (Wüster, c) = -63.64 kcal. mole⁻¹, the value of $\Delta H_f^{298.15}(\text{Fe}_3\text{O}_4, c)$ was calculated as -266.5 kcal. mole⁻¹. The enthalpy change, $\Delta H_f^{298.15} = 4.33$ kcal. mole⁻¹, for the reaction $3\text{Fe}(c) + 4\text{CO}_2(g) = \text{Fe}_3\text{O}_4(c) + 4\text{CO}(g)$ was reported by L. S. Darken and R. W. Gurry, J. Am. Chem. Soc. 68, 798 (1946). The corresponding $\Delta H_f^{298.15}(\text{Fe}_3\text{O}_4, c)$ was evaluated as -266.22 kcal. mole⁻¹. The adopted value of $\Delta H_f^{298.15}$ for $\text{Fe}_3\text{O}_4(c)$ is selected as -267.9 ± 0.2 kcal. mole⁻¹.

Heat Capacity and Entropy.

The low temperature (60.5-299.7°K.) heat capacities were reported by R. W. Millar, J. Am. Chem. Soc. 51, 215 (1929). The high temperature (298-1800°K.) heat capacities were obtained from J. P. Coughlin, E. G. King and K. R. Bonnickson, J. Am. Chem. Soc. 73, 3891 (1951). These two sets of data were plotted and joined smoothly at 298°K. The C_p values above 1800°K. were obtained by graphical extrapolation. Heat capacities (90-295°K.) for $\text{Fe}_3\text{O}_4(c)$ were also reported by O. S. Parks and K. K. Kelley, J. Phys. Chem. 50, 47 (1946). $S_{298.15}^\circ(\text{Fe}_3\text{O}_4, c)$ was derived from the smoothed C_p data mentioned previously, using $S_{44.7}^\circ = 0.969$ e.u. J. P. Coughlin, E. G. King and K. R. Bonnickson, loc. cit. measured the heat-content for magnetite and found a magnetic anomaly around 880°K., corresponding to a maximum in heat capacity. A maximum heat capacity of 37.1 cal. deg.⁻¹ mole⁻¹ at 114.15°K. was also reported by R. W. Millar, loc. cit.

Melting Data.

T_m and ΔH_m^0 were obtained from L. S. Darken and R. W. Gurry, loc. cit.

Heat of Formation.

The heat of formation was calculated from $D_0^{\circ}(\text{H}_2) = 36113.0 \pm 0.3 \text{ cm.}^{-1}$, reported by G. Herzberg and A. Monfils, *J. of Molecular Spectroscopy* 5, 482 (1960). This value was measured more precisely than the value $D_0^{\circ}(\text{H}_2) = 36116 \pm 6 \text{ cm.}^{-1}$ by H. Baulier, *Z. Phys. Chem. B29*, 315 (1935).

Heat Capacity and Entropy.

Electronic levels taken from C. E. Moore, *Natl. Bur. Standards (U. S.) Circ. 467* (1949).

PROTON (H⁺)

(IDEAL GAS)

GFW = 1.00742

ΔH_{f,0}^o = 365.236 ± 0.01 kcal/molΔH_{f,298.15}^o = 367.186 ± 0.01 kcal/molS_{298.15}^o = 26.012 gibbs/mol

Heat of Formation.

The heat of formation was calculated from the equation $H(g) \rightarrow H^+(g) + e^-$ with the JANAP auxiliary data for $H(g)$, using an ionization potential = 13.598 eV (313.605 kcal/mol) for $H(g)$ obtained from C. W. Beckett, National Bureau of Standards Report 8628, Jan. 1, 1965.

Heat Capacity and Entropy.

Calculated by assuming the proton to be an ideal monatomic gas. The enthalpy between 298° and 0°K is 1.481 kcal/mol as for all unexcited monatomic gases.

0	1

Heat of Formation.

The heat of formation was calculated from the equation: $H(g) + e^- \rightarrow H^-(g)$ with the JANAF auxiliary value for $H(g)$ (this supplement), using an I.P. = $6.083098 \times 10^5 \text{ cm}^{-1}$ (.754 e.v. or 17.39 kcal/mole) for $H^-(g)$ obtained from C. L. Pekeris, Phys. Rev. **125**, 1470 (1962). The I.P. value for $H^-(g)$ reported by C. W. Scherr and R. E. Knight, Rev. Mod. Phys. **35**, 436 (1963) is in agreement with the value of Pekeris.

Heat Capacity and Entropy.

The electronic levels and quantum weights were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, U. S. National Bureau of Standards Circular 467, June 15, 1949, by assuming that the extra electron would produce an electronic configuration similar to that of the next higher atomic numbered element, in this case Helium. The electronic levels above $1 \times 10^5 \text{ cm}^{-1}$ were omitted because their contribution is negligible below 6000°K. The H°_{298} value at 0°K. is -1.481 kcal/mole.

Sept. 30, 1965

Heat of Formation.

The heat of formation was calculated from D_0 , 8.671 kcal. mole⁻¹, taken from G. Herzberg, "Spectra of Diatomic Molecules," 2nd Edition, D. Van Nostrand Company, Inc., New York (1950).

Heat Capacity and Entropy.

Molecular constants were taken from G. Herzberg, loc. cit.

HYDROGEN IODIDE (HI)

(IDEAL GAS)

MOL. WT. = 127.918

$$\Delta H_f^\circ = 6.82 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\Delta F_f^\circ = 6.82 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\Delta G_f^\circ = 6.82 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\omega_e = 2309.06 \text{ cm}^{-1}$$

$$\omega_e = 39.73 \text{ cm}^{-1}$$

$$B_e = 6.512 \text{ cm}^{-1}$$

$$\alpha_e = 0.1715 \text{ cm}^{-1}$$

Thermodynamic Functions.

Molecular constants are from M. Cowan and W. Gordy [Phys. Rev. 104, 551 (1956)] and D. R. J. Boyd and H. W. Thompson [Spectrochim. Acta 5, 308 (1952)]. The calculated functions are in reasonable agreement with the compilation of K. K. Kelley [U. S. Bur. Mines Bull. 564 (1960)].

Heat of Formation.

Using the calculated functions derived above and functions for $H_2(g)$ and $I_2(g)$ given in the JANAF tables, equilibrium data from the literature were used to calculate ΔH_{298}° for the reaction

$$\Delta H_{298}^\circ, \text{ kcal. mole}^{-1}$$

Taylor and Crist ¹ (667° to 764°K)	-2.375 ± .005
Bodenstein ² (556° to 781°K)	-2.053 ± .135
Bright and Hagerty ³ (696° and 779°K)	-2.219 ± .070
Rittenberg and Urey ⁴ (671° and 741°K)	-2.156 ± .072

The data of Taylor and Crist are the most concordant and are given the most weight. Converting to the solid state of iodine, which has been adopted as a JANAF reference state gives the standard heat of formation of hydrogen iodide.

 $\Delta H_f^0 = \text{Unknown}$ $\Delta H_f^0 298.15 = -13.819 \pm 0.011 \text{ kcal. mole}^{-1}$ $S_{298.15}^0 = [12] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $T_d = [690]^{\circ}\text{K.}$

Heat of Formation.

The value of $\Delta H_f^0 298.15$ was taken from S. R. Gunn and L. G. Green, J. Am. Chem. Soc. **80**, 4782 (1958). The corresponding value reported by C. E. Measer, L. G. Fasolino and C. E. Thalmeier, J. Am. Chem. Soc. **77**, 4524 (1955) was $-15.16 \pm 0.6 \text{ kcal. mole}^{-1}$. In this paper the results of the previous investigations were also reviewed.

Heat Capacity and Entropy.

C_p and $S_{298.15}^0$ were estimated by comparison with those for NaH(c) and LiH(c).

Temperature of Decomposition.

T_d was assumed to be the temperature at which the value of ΔF_f^0 changes from negative to positive.

Dec. 31, 1961; Mar. 31, 1962; June 30, 1962; Mar. 31, 1966

POTASSIUM HYDROXIDE (KOH)

(CRYSTAL)

MOL. WT. = 56.10937

S_{298.15} = 18.95 cal. deg.⁻¹ mole⁻¹
 T_m = 522°K
 T_m = 673°K.

ΔH°_f 0 = -100.7 ± 0.1 kcal. mole⁻¹
 ΔH°_f 298.15 = -101.5 ± 0.1 kcal. mole⁻¹
 ΔH°_f = 1.515 kcal. mole⁻¹
 ΔH°_f = 2.240 kcal. mole⁻¹
 ΔH°_f 298.15 (to monomer) = [46.1] kcal. mole⁻¹
 ΔH°_f 298.15 (to dimer) = [45.6] kcal. mole⁻¹

Heat of Formation.

The standard enthalpy of formation, ΔH°_f 298 (KOH, c) = -101.5 ± 0.1 kcal. mole⁻¹, was calculated from the heat of solution of KOH(c), the heat of hydrolysis of potassium metal and the appropriate auxiliary data.

N. A. Feshetnikov¹ has measured the heat of solution KOH(c) → KOH(650 H₂O) as -13.665 ± 0.009 kcal. mole⁻¹ at 298.15°K. in the solution calorimeter. Using the auxiliary heat of dilution reported by V. B. Parker², the selected heat of solution of KOH(c) at infinite dilution is -13.770 kcal. mole⁻¹. The heat of solution KOH(c) → KOH(25 H₂O) has also been measured as -13.80 ± 0.10 kcal. mole⁻¹ in the solution calorimeter by W. E. Hatton, D. L. Hildenbrand, G. C. Sinke and D. R. Stull³. Both results are in good agreement.

The heat of hydrolysis of potassium metal, ΔH°_f 298, has been measured in the solution calorimeter by the following investigators.

Source	Number of Moles of H ₂ O	ΔH° _f 298 kcal. mole ⁻¹	ΔH° _f 298 (KOH(∞ H ₂ O)) kcal. mole ⁻¹	ΔH° _f 298 (KOH, c) kcal. mole ⁻¹
Gunn et al. ⁴	1000	-46.877 ± 0.01	-115.281	-101.511
Messer et al. ⁵	∞	-47.02 ± 0.15	-115.335	-101.565
Ketchen et al. ⁶	∞	-46.894 ± 0.24	-115.209	-101.439

The values of ΔH°_f 298 (KOH(∞ H₂O)) were calculated from the heats of reaction, ΔH°_r 298, using ΔH°_f 298 (H₂O, l) = -68.315 kcal. mole⁻¹. Combination of the selected heat of solution of KOH(c) at infinite dilution with the heat of formation of KOH(∞ H₂O) gives the heat of formation of KOH(c) in the last column of the table. A weighted average of these three measurements was taken for the selected heat of formation of KOH(c).

The earlier investigations have been reviewed by F. R. Bichowsky and F. D. Rossini⁸ and C. E. Messer et al.⁵, and these earlier reported data are not adopted in the tabulation.

Heat Capacity and Entropy.

The low temperature heat capacities of KOH(c) from 15° to 340°K. have been measured by W. E. Hatton et al.³ who have also observed a sharp peak in the heat capacity curve in the temperature range from 210° to 230°K. These values of C_p were adopted in the calculation. W. D. Powers and G. C. Blalock⁹ have measured the high temperature enthalpy changes of the solid KOH in the α and β phases by the drop method. Their enthalpy data are scattered and not precise enough to accurately define the heat capacities in the α phase. Therefore, the selected heat capacities between 340° and 522°K. were estimated from a graphical extrapolation of the low temperature heat capacity curve, and the tabulated H°-H°₂₉₈ functions are in agreement with their enthalpy measurements within the experimental uncertainty. The heat capacities of KOH(c) in the β phase were obtained from Powers and Blalock⁹.

The entropy (S°₂₉₈ = 18.95 cal. deg.⁻¹ mole⁻¹) was taken from Hatton et al.³, based on an extrapolation of S°₁₅ = 0.054 cal. deg.⁻¹ mole⁻¹.

Transition and Melting Data.

Hatton et al.³ have found a lambda transition at 227.4°K. in the heat capacity measurement. The adopted heat of α-β transition at 522°K. and heat of melting at 673°K. were obtained from Powers and Blalock⁹. P. S. Seward and K. E. Martin¹⁰ found ΔH°_m = 1.83 kcal. mole⁻¹ at 683°K. In phase diagram studies of the system KOH-K₂CO₃.

Heat of Sublimation.

See KOH(g) table for details.

Dec. 31, 1961; Mar. 31, 1962; Sep. 30, 1962; Mar. 31, 1966

$S_{298.15}^o = 23.518$ cal. deg.⁻¹ mole⁻¹
 $T_m = 675^\circ\text{K.}$
 T_b (monomeric gas) = 1600°K.
 ΔH_f^o (to monomer) = 32.0 kcal. mole⁻¹

Heat of Formation.

The heat of formation of KOH(l) at 298°K. was obtained from that of the crystal by adding ΔH_m^o and the difference between H_{675}^o - H_{298}^o for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase, $C_p = 19.86$ cal. deg.⁻¹ mole⁻¹, was obtained from the enthalpy measurements in the drop calorimeter by W. D. Powers and G. C. Bialook, ORNL-1653, Oak Ridge Nat'l. Lab., Jan. 1954. The constant C_p was extrapolated below the melting point and up to 2500°K.

The entropy, $S_{298.15}^o = 23.51$ cal. deg.⁻¹ mole⁻¹, was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See KOH(c) table for details.

Vaporization Data.

The boiling point 1600°K. was calculated as the temperature at which the free energies of formation (ΔF_f^o) for both KOH(l) and KOH(g) are equal. The difference in the heats of formation (ΔH_f^o) of KOH(l) and KOH(g) at the boiling point is the heat of vaporization. If $K_2(OH)_2(g)$ is also considered as a minor component in the vapor mixture (approximately 2% of total vapor pressure at the boiling point) the calculated boiling point is unchanged as 1600°K. (see KOH(g) table for details).

H. von Wartenberg and P. Albrecht, Z. Elektrochem. **21**, 162 (1921), have studied the vapor pressures of liquid KOH and reported the boiling point as 1597°K.

Heat of Formation.

R. F. Porter and R. C. Schoonmaker, J. Phys. Chem. 62, 234 and 486 (1958), have investigated the potassium hydroxide vapor by the mass-spectrometric method and found that the KOH vaporizes mainly as gaseous dimer in the temperature range from 573° to 723°K. Later, Schoonmaker and Porter, J. Chem. Phys. 31, 830 (1959), found the activity of molten alkali hydroxide had been reduced in the presence of MgO in their sample container. Using the reported partial pressures of KOH(g) and K₂(OH)₂(g) at 641° and 666°K. and JANAF free energy functions, the third law calculations give ΔH_f⁰ 298 = -45.4 ± 5 kcal. mole⁻¹ for 2KOH(g) → K₂(OH)₂(g), and ΔH_f⁰ 298 = 45.41 ± 3.5 kcal. mole⁻¹ for KOH(g), and ΔH_f⁰ 298 = 45.6 ± 5 kcal. mole⁻¹ for 2KOH(g) → K₂(OH)₂(g). The uncertainties given were derived by assuming K₂ to be good to a factor of 5 as stated by the authors and including an extra factor of 2 as possible error in activity. To this was added an estimate of the uncertainty due to functions used. In order to have good agreement between the calculated total pressures of monomeric and dimeric KOH(g) and the observed vapor pressures measured by H. von Wartenberg and F. Albrecht, Z. Elektrochem. 27, 182 (1921), the heat of sublimation to monomeric gas was adjusted to ΔH_g⁰ 298 (to monomer) = 46.08 kcal. mole⁻¹. (The heat of sublimation to dimeric gas was unchanged as ΔH_g⁰ 298 (to dimer) = 45.64 kcal. mole⁻¹). The calculated boiling point is 1600°K. which is in good agreement with 1597 ± 10°K. reported by Wartenberg and Albrecht. The heats of formation were calculated from the selected heats of sublimation as ΔH_f⁰ 298(KOH,g) = -55.4 and ΔH_f⁰ 298(K₂(OH)₂,g) = -157.4 kcal. mole⁻¹.

Heat Capacity and Entropy.

The bond distance K-O was estimated by adding the bond length difference (0.04 Å) between H-OH(g) and H-F(g) to the bond distance K-F(g) (2.17145 Å) which has been accurately measured by R. K. Ritchie and H. Lew, Can. J. Phys. 42, 43 (1964). The bond distance O-H was estimated from that in H₂O(g). The bent molecular configuration with the bond angle of 110° has been proposed by S. H. Bauer, R. M. Diner and R. F. Porter, J. Chem. Phys. 29, 931 (1958), but a linear model has also been suggested by R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. 31, 830 (1959). The bent model has been adopted in the tabulation. The three principal moments of inertia are: I_A = [0.1256] × 10⁻³⁹, I_B = [9.8070] × 10⁻³⁹ and I_C = [9.9326] × 10⁻³⁹ g. cm.².

The K-O stretching frequency (408 cm.⁻¹) was obtained from L. H. Spinar and J. L. Margrave, Spectrochim. Acta 12, 244 (1957) in the infrared spectroscopic studies. The O-H stretching and the bending frequencies were estimated by comparison with H-OH, D-OH and T-OH which indicate rapid convergence to a constant as a heavier atom is attached.

L. Brewer and D. F. Mastick, J. Am. Chem. Soc. 73, 2045 (1951), have calculated theoretically the bond distances of gaseous alkali oxides (Li-O = 1.52 Å, Na-O = 1.94 Å and K-O = 2.27 Å) which have been quoted by Bauer, Diner and Porter, loc. cit., and many other authors.

Heat of Formation

The heats of solution of Li(c) and LiH(c) in water have been measured by Guntz (1) and Moers (2) using an open Dewar flask calorimeter and by Messer (3) and Gunn (4) using closed bomb calorimetry. Based on the reported values of the enthalpy changes (ΔH°) for the reaction (A) $\text{Li(c)} + \text{H}_2\text{O(l)} = \text{LiOH(aq)} + 1/2\text{H}_2\text{(g)}$, and (B) $\text{LiH(c)} + \text{H}_2\text{O(l)} = \text{LiOH(aq)} + \text{H}_2\text{(g)}$, the corresponding ΔH°_{298} for LiH(c) are calculated. The results are presented in the table below.

The decomposition pressures of LiH(c) have been determined by Hurd (5), at temperatures 782 - 928°K. By use of the second and third law methods, the enthalpy changes for the decomposition reaction (C) $\text{LiH(c)} = \text{Li(l)} + 1/2\text{H}_2\text{(g)}$ are evaluated as 21.87 ± 0.3 and 22.34 kcal/mol , respectively. Based on the third law ΔH°_{298} and $\Delta H^{\circ}_{298}(\text{Li, l}) = 0.569 \text{ kcal/mol}$, we derive the value $\Delta H^{\circ}_{298}(\text{LiH, c}) = -21.77 \pm 0.2 \text{ kcal/mol}$, which is in good agreement with the values obtained by calorimetric method. Guntz (1) measured the decomposition pressure at 953°K for the same reaction. The third law ΔH°_{298} and $\Delta H^{\circ}_{298}(\text{LiH, c})$ are evaluated as 21.86 and -21.29 kcal/mol , respectively.

Johnson (6) has determined the standard Gibbs energy of formation (ΔG°) for LiH(c) from emf measurements over the temperature range 875 - 885°K. The cell utilized an Amoco Iron flag over which H_2 was passed as the cathode and a molten Li anode. LiCl, LiBr and LiI, each saturated with LiH, were used as electrolytes. Using the reported emf values at different temperatures (47 data points) for reaction (C), we derive a $\Delta H^{\circ}_{298} = -21.81 \text{ kcal/mol}$ for LiH(c). The $\Delta H^{\circ}_{298}(\text{LiH, c})$ value reported by Gunn (4) is adopted.

Investigator	Reaction A	Reaction B	Reaction C	Drift eu	ΔH°_{298} kcal/mol

6. Johnson (1966)	-	-	22.38	1.0±0.2	-21.81±0.15

Heat Capacity and Entropy

The low temperature heat capacities are obtained from the data of Kostyukov (7), 3.72 - 285.5°K. The cp data reported by Gunther (8) are consistently lower than the adopted ones in the temperature range 74.0 - 90.5°K but considerably higher at 292.7°K. The high temperature enthalpies have been determined by Fieldhouse (9), 413.2 - 914.3°K, and Vogt (14), 878.15 - 953.15°K. The derived high temperature heat capacities are joined smoothly with the low temperature values and extrapolated smoothly above 953.15°K.

S°_{298} is calculated based on the adopted low temperature heat capacities, using $S^{\circ}_0 = 0.0002 \text{ eu}$.

Melting Data

The value of T_m has been reported as 953 (1), 961 ± 1 (10, 12), 959.6 (11), and 961.8 ± 0.3 (13). The value reported by Messer (13) is adopted. The heat of melting (ΔH_m°) has been determined as 5.095 ± 0.46 (13) and $5.237 \pm 0.040 \text{ kcal/mol}$ (14). The first ΔH_m° value was evaluated cryogenically from the lowering of melting point in the systems LiH-Li₂O and LiH-CaH₂.

The second value was derived from enthalpy data measured with copper block calorimeter. The adopted ΔH_m° value is derived from the enthalpy data of Vogt (14) using the adopted heat capacities for LiH(c) and LiH(l).

Heat of Sublimation

The value of ΔH°_{298} is calculated as the difference between ΔH°_{298} for LiH(g) and LiH(c).

LITHIUM HYDRIDE (LiH)

(LIQUID)

GFW = 7.94697

 $S^\circ_{298.15} = 5.314 \text{ gibbs/mol}$ $\Delta H^\circ_{298.15} = -18.573 \text{ kcal/mol}$ $T_m = 961.8 \pm 0.3^\circ\text{K}$ $\Delta H_m^\circ = 5.40 \pm 0.10 \text{ kcal/mol}$ $T_d = 1223^\circ\text{K}$

Heat of Formation

 $\Delta H^\circ_{298}(\ell)$ is obtained from $\Delta H^\circ_{298}(c)$ by adding ΔH_m° and the difference between $H^\circ_{961.8} - H^\circ_{298}$ for crystal and liquid.

The decomposition pressures of $\text{LiH}(\ell)$ at different temperatures have been investigated by Hill (1), Perlow (2), Johnson, and Gibb (3). Based on their reported equilibrium pressures, the enthalpy changes for the reaction $\text{LiH}(\ell) = \text{Li}(\ell) + 1/2\text{H}_2(\text{g})$ are evaluated by the second and third law methods. The results are presented in the table below. It should be noted that the measured decomposition pressures are highly sensitive to composition and change extremely rapidly between 99 and 100 percent purity. Therefore we give no weight to the equilibrium data.

Investigator	Temperature, °K	No. of Points	ΔH°_{298} , kcal/mol		ΔH°_{298} , **
			Second Law	Third Law	
Hill (1938)	973.2	1	—	16.93	—
Perlow (1941)	1043-1098	2	20.10	17.69	-2.2
Johnson*	1050-1090	—	24.69	18.36	-5.9
Gibb (1951)	1073-1173	2	5.66	15.2	+8.5

*The vapor pressure values are calculated from an equation quoted by Gibb (3), but derived from the vapor pressures measured by W. C. Johnson, University of Chicago.

**Based on the third law ΔH°_{298} .

Heat Capacity and Entropy

The enthalpies of $\text{LiH}(\ell)$ in the temperature range 975.15-1075.15°K have been measured by Vogt (5). Using the reported enthalpy values, the heat capacity of $\text{LiH}(\ell)$ is derived as 14.9 gibbs/mol. This Cp value is adopted and extrapolated above and below the measured range.

The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See $\text{LiH}(c)$ table for details.

Decomposition Temperature

T_d is calculated as the temperature at which $\text{LiH}(\ell)$ decomposes into $\text{Li}(\ell)$ and $\text{H}_2(\text{g})$ where the partial pressure of $\text{H}_2(\text{g})$ equals one atmosphere.

Heat of Formation

R. Velasco, Can. J. Phys. **35**, 1204 (1957), observed the absorption spectra of LiH(g) in the near ultraviolet with high dispersion and absorbing path lengths up to 16 meters. He found a new band system involving the ground state and a $^1\Pi$ excited state. Rotational and vibrational analyses of this system were carried out and the observed breaking off of the rotational structure of the bands was interpreted as due to predissociation by rotation. With this assumption very accurate dissociation limits of the $B^1\Pi$ state were obtained. From these dissociation limits the dissociation energy (D_0) of the ground state of LiH was found to be $2.4288 \pm 0.0002 \text{ eV}$. Based on this D_0 value, we adopt $\Delta H_f^\circ = 33.61 \text{ kcal/mol}$ for LiH(g).

W. Kemperer, J. Chem. Phys. **23**, 2452 (1955), observed the infrared spectrum of LiH(g) in emission in the frequency region 1500 to 970 cm^{-1} , using a Perkin-Elmer double-pass monochromator with NaCl optics. Estimating the minimum LiH pressure as 10 mm and assuming the maximum possible Li pressure, he reported $K = 0.005 \text{ (atm)}$ at 1400°K for the reaction $2\text{Li(g)} + \text{H}_2\text{(g)} = 2\text{LiH(g)}$. We calculate the corresponding enthalpy change, ΔH_{1400}° , to be -9.63 kcal/mol , employing $\Delta S_{1400}^\circ = -17.407 \text{ eu}$. Incorporating this ΔH_{1400}° value with $\Delta H_f^\circ = 35.601 \text{ kcal/mol}$ for Li(g), we obtain $\Delta H_f^\circ = 33.92 \text{ kcal/mol}$ for LiH(g), which is in good agreement with the adopted value.

A. G. Gaydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953, derived the value $D_0(\text{LiH}) = 2.5 \pm 0.2 \text{ eV}$ from earlier spectroscopic data.

Heat Capacity and Entropy

The third electronic level and quantum weight are obtained from Velasco, loc. cit. All the other constants are taken from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., and corrected to the average isotopic species. The moment of inertia is $3.7193 \times 10^{-40} \text{ g cm}^2$.

S₂₉₈⁰ = 10.225 cal. deg.⁻¹ mole⁻¹
 T_m = 744.3°K.

Heat of Formation.

The standard enthalpy of formation, ΔH_f⁰ 298 (LiOH, c) = -115.84 ± 0.1 kcal. mole⁻¹, was calculated from the heat of solution of lithium hydroxide (c), the heat of hydrolysis of lithium metal and the appropriate auxiliary data. N. A. Fessenden⁷ has measured the heat of solution LiOH(c) → LiOH(400 H₂O) as -5.479 ± 0.007 kcal. mole⁻¹ at 298.15°K. by solution calorimetry. Using the auxiliary heat of dilution reported by V. B. Parker², the selected heat of solution of lithium hydroxide (c) at infinite dilution is -5.632 kcal. mole⁻¹.

The heat of hydrolysis of lithium metal, ΔH_f⁰ 298, has been measured in the solution calorimeter by the following investigators.

Source	Number of moles of H ₂ O	ΔH _f ⁰ 298 kcal. mole ⁻¹	ΔH _f ⁰ 298 (LiOH(c)) kcal. mole ⁻¹	ΔH _f ⁰ 298 (LiOH, c) kcal. mole ⁻¹
Gunn et al. ³	1000	-53.115 ± 0.019	-121.532	-115.900
Messer et al. ⁴	∞	-53.075 ± 0.20	-121.380	-115.758

The values of ΔH_f⁰ 298 (LiOH(c)) were calculated from the heats of reaction ΔH_f⁰ 298, using the ΔH_f⁰ 298 (H₂O, l) = -68.315 kcal. mole⁻¹.⁵ Combination of the selected heat of solution of LiOH(c) at infinite dilution with the heat of formation of LiOH(c) gives the heat of formation of LiOH(c) in the last column of the table. A weighted average of these measurements was taken for the adopted heat of formation of lithium hydroxide (c).

The earlier calorimetric investigations have been reviewed by P. R. Bichowsky and P. D. Rossini⁶, and C. E. Messer et al.⁴, and these data are not adopted in the tabulation.

Heat Capacity and Entropy.

The low temperature heat capacities of lithium hydroxide (c) from 15.91° to 302.85°K. have been measured by T. W. Bauer, H. L. Johnston and E. C. Kerr.⁷ The high temperature heat capacities which were determined from the enthalpy measurements in the temperature range from 418° to 876°K. by the drop method have been reported by C. H. Shomate and A. J. Cohen.⁸ The low temperature and the high temperature heat capacities have been joined smoothly by the Shomate method.⁹ The smooth values of heat capacity of LiOH(c) were adopted in the tabulation.

W. D. Powers and O. C. Blalock¹⁰ have also measured the high temperature enthalpy changes of LiOH(c) by the drop method. Their results are in agreement with the tabulated H_m-H₂₉₈ values within the experimental uncertainty. The entropy (S₂₉₈⁰ = 10.225 cal. deg.⁻¹ mole⁻¹) was obtained from Bauer et al.⁷, based on an extrapolation of S₁₆⁰ = 0.028 cal. deg.⁻¹ mole⁻¹.

Melting Data.

The adopted heat of melting and the melting point were obtained from the enthalpy measurements by Shomate and Cohen.⁸ Powers and Blalock¹⁰ also found the heat of melting ΔH_m⁰ = 5.029 kcal. mole⁻¹ at 746°K. which is in good agreement with the adopted value.

Dec. 31, 1960; Mar. 31, 1966

S_{298.15} = 11.574 cal. deg.⁻¹ mole⁻¹
 T_m = 744.3°K.
 T_b(monomeric gas) = 1803°K.
 ΔH_f° 298.15 = -113.263 kcal. mole⁻¹
 ΔH_m° = 5.010 kcal. mole⁻¹
 ΔH_v°(to monomer) = 40.1 kcal. mole⁻¹

Heat of Formation.

The heat of formation of LiOH(l) at 298.15°K. was obtained from that of the crystal by adding ΔH_m° and the difference between H_{744.3}°K. 298.15 for crystal and liquid.

Heat Capacity and Entropy.

The selected heat capacity of the liquid phase, C_p = 20.74 cal. deg.⁻¹ mole⁻¹, was obtained from the enthalpy measurements in the drop calorimeter by C. H. Shomate and A. J. Cohen, J. Am. Chem. Soc. **77**, 285 (1955).

W. D. Powers and G. C. Blalock, ORNL-1653, Oak Ridge Nat'l. Lab., have also determined the heat capacity of lithium hydroxide (l), C_p = 22.03 cal. deg.⁻¹ mole⁻¹, from the enthalpy measurements by the drop method.

The entropy (S_{298.15} = 11.574 cal. deg.⁻¹ mole⁻¹) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See LiOH(c) table for details.

Vaporization Data.

The boiling point was calculated as the temperature at which the free energies of formation (ΔF_f°) for both LiOH(l) and LiOH(g) are equal. The difference in the heats of formation (ΔH_f°) of LiOH(l) and LiOH(g) at the boiling point is the heat of vaporization (ΔH_v°).

Heat of Formation

J. Berkowitz, D. J. Menchi and M. A. Chupka, J. Chem. Phys. 33, 535 (1960), have studied the equilibrium of $\text{Li}_2\text{O}(c) + \text{H}_2\text{O}(g)$ system by the mass-spectrometric method. Using the reported equilibrium constants in the temperature range from 1100° to 1450°K , the heat of reaction $\text{Li}_2\text{O}(c) + \text{H}_2\text{O}(g) \rightarrow 2\text{LiOH}(g)$ at 298.15°K has been calculated by both the second and the third law methods as 86.1 and $83.2 \text{ kcal. mole}^{-1}$, respectively. (The third law drift is $-2.2 \pm 2.6 \text{ e.u.}$) The third law value was taken for the calculation of the heat of formation of $\text{LiOH}(g)$ at 298.15°K .

Heat Capacity and Entropy

Since the bond distance Li-F(g) ($r_e = 1.56389 \text{ \AA}$) was accurately measured from the microwave studies by L. Wharton, W. Klempner, L. P. Gold, R. Strauch, J. J. Gallagher and V. E. Derr, J. Chem. Phys. 39, 1203 (1963), the bond distance Li-O in $\text{LiOH}(g)$ was estimated by adding the bond length difference (0.04 \AA) between H-OH(g) and H-F(g) to the bond distance Li-F(g). Also the bond distance Li-O(g) was estimated as 1.62 \AA from the matrix-isolated infrared spectrum by D. White, K. S. Seshadri, D. F. Dever, D. E. Mann, M. J. Linevsky, J. Chem. Phys. 39, 2463 (1963). These two are in good agreement. The bond distance O-H was estimated from that in $\text{H}_2\text{O}(g)$. The adopted bent molecular configuration with bond angle of 110° was proposed by S. H. Bauer, R. M. Diner and P. F. Porter, J. Chem. Phys. 29, 991 (1958). The three principal moments of inertia are $I_A = [0.1237] \times 10^{-39}$, $I_B = [2.1699] \times 10^{-39}$ and $I_C = [2.2956] \times 10^{-39} \text{ g. cm.}^2$.

The Li-O stretching frequency was estimated to be the same as that in $\text{Li}_2\text{O}(g)$ ($\nu = 987 \text{ cm.}^{-1}$, see $\text{Li}_2\text{O}(g)$ table). The bending and the O-H stretching frequencies were estimated by comparison with H-OH, D-OH and T-OH which indicate rapid convergence to a constant as a heavier atom is attached.

Heat of Formation.

The heat of formation is calculated using $D_0^\circ = 2.0 \pm 0.5$ e.v. derived from a graphical extrapolation of the $V(0-3)$ energy levels of the $X^2\Sigma^+$ state reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," 2nd Edition, Chapman and Hall Ltd., London, 1953. G. Herzberg, "Molecular Spectra and Molecular Structure, I. Spectra of Diatomic Molecules," 2nd Edition, D. Van Nostrand Co., Inc., New York, 1950, reported $D_0^\circ \leq 2.49$ e.v. assuming predissociation of the $c^4\Pi$ state of MgH into $\text{Mg}(^3P)$ and $\text{H}(^2S)$.

Heat Capacity and Entropy.

The molecular constants and electronic levels are obtained from Herzberg, loc. cit., except for the electronic levels 35400 and 48000 obtained from M. A. Khan, Proc. Phys. Soc. (London) **80**, 209 - 21 (1962).

Heat of Formation

The heat of formation is based on the following estimates. The relation D₀⁰(M-X)/D₀⁰(X-H-X) = 0.46 ± 0.03 for several alkaline earth dihalides has been reported by R. A. Kent, J. D. McDonald and J. L. Margrave, J. Phys. Chem. 70, 874 (1966). Assuming that this relation applies to hydroxides, we may estimate D₀⁰(Mg-OH) = 87 ± 12 kcal/mol. A value of D₀⁰(Mg-OH) = 105 ± 12 kcal/mol is obtained by comparison with D₀⁰(Be-OH) = 111 ± 10, D₀⁰(Ca-OH) = 100 ± 10 and D₀⁰(Sr-OH) = 95 ± 10 kcal/mol. The value for BeOH is from the JANAF tables, while those for CaOH and SrOH are from flame studies of L. V. Gurvich, private communication, High Temperature Institute, Moscow, 1966. The average value of D₀⁰(Mg-OH) = 96 kcal/mol is used to calculate the heat of formation.

A value of D₀⁰(Mg-OH) = 56 ± 5 kcal/mol was derived from intensity measurements on the flame spectrum of magnesium by E. M. Bulewicz and T. M. Sugden, Trans. Faraday Soc. 55, 770 (1959). This appears to be too small.

Heat Capacity and Entropy

The ground state is assumed to be ²Σ by analogy with isoelectronic MgF. Ultraviolet emission spectra near 3800 Å were observed for MgOH and MgOD by D. Pesic and A. G. Gaydon, Proc. Phys. Soc. (London) 73, 244 (1959), and L. Brewer and S. Trajmar, J. Chem. Phys. 36, 1585 (1962). Vibrational and rotational analyses were not performed. Assuming that the observed spectra correspond to the transition A²Π + X²Σ, we estimate the first excited state at 27000 cm⁻¹. The vibrational frequencies ν₁ and ν₃ are estimated from those of H₂O(g) and MgO(g). The ν₂ is tentatively estimated at 1000 cm⁻¹.

A linear structure is assumed by use of the prediction of A. D. Walsh, J. Chem. Soc. 1953, 2288 (1953), for "HAB" molecules with less than 11 valence electrons (MgOH has 9 valence electrons). Confirmation of this prediction is scanty for molecules having "A" as the most electronegative element; however, recent microwave evidence [R. L. Kuczkowski, D. R. Lide, Jr., and L. C. Krishner, J. Chem. Phys. 44, 3131 (1966)] for the linearity of KOH and CaOH confirms the prediction for these molecules having 8 valence electrons. The O-H bond distance is assumed to be the same as that of H₂O(g) and the Mg-O bond distance is estimated from that of MgO(g).

MAGNESIUM MONOHYDROXIDE UNIPOSITIVE ION (MgOH⁺)

GFW = 41.31882

(IDEAL GAS)

Point Group [C_{∞v}]
 $S_{298.15}^o = [51.9 \pm 2] \text{ gkcal/mol}$
 $\Delta H_{298.15}^o = [144 \pm 40] \text{ kcal/mol}$

Ground State Quantum Weight = 1

Vibrational Frequencies and Degeneracies

ω_e, cm^{-1}

[800] (1)

[900] (2)

[3500] (1)

O-H = [0.96] Å

$\sigma = 1$

Bond Distance: Mg-O = [1.8] Å

Bond Angle: Mg-O-H = [180°]

Rotational Constant: $B_0 = [0.4765] \text{ cm}^{-1}$

Heat of Formation

The gaseous molecules NaOH, MgOH and AlOH have 8, 9 and 10 valence electrons, respectively. Due to the similarity in molecular structure, we assume that the ionization potential (IP) of MgOH is approximately the average of IP(NaOH) and IP(AlOH). Adopting IP = 9 and 7.5 eV for NaOH (2) and AlOH (2), respectively, we obtain IP(MgOH) = 8.5 eV. Based on this value and $\Delta H_{298.15}^o(\text{MgOH}, g) = -52 \pm 20 \text{ kcal/mol}$ we derive $\Delta H_{298.15}^o(\text{MgOH}^+, g) = 143 \pm 40 \text{ kcal/mol}$ which is tentatively adopted. The estimated value IP(MgOH) is close to IP(MgF) = $7.8 \pm 0.3 \text{ eV}$ (1), where MF and MgOH are isoelectronic molecules, and thus confirms the value within its uncertainty.

Heat Capacity and Entropy

Walsh (3) predicted that ABH molecules (H = hydrogen atom) containing 10 or less valence electrons will be linear in their ground state. Since MgOH⁺ molecule has 8 valence electrons, we assume it to be linear. The vibrational frequencies are estimated by comparison with those for NaOH(g) and MgOH(g). The O-H bond distance is assumed to be the same as that in H₂O(g). The Mg-O bond distance is estimated (4). The moment of inertia is $5.874 \times 10^{-39} \text{ g cm}^2$. The ground state quantum weight is assumed to be the same as that of NaOH(g). The enthalpy at 0°K is -2.24 kcal/mol .

Heat of Formation.

The value, $\Delta H_f^\circ 298 (\text{NH}, g) = 81.0 \pm 2.5 \text{ kcal. mole}^{-1}$, was calculated from the selected dissociation energy, $D_0 = 83 \pm 2 \text{ kcal. mole}^{-1}$, based on the following investigations. J. L. Franklin, V. H. Disher, R. M. Reese and M. Krause, *J. Am. Chem. Soc.* 80, 298 (1958) and R. I. Reed and V. Sneeden, *J. Chem. Soc.* 4132 (1959) have determined the dissociation energy of $\text{NH}(g)$ by electron impact as $83 \pm 2 \text{ kcal. mole}^{-1}$ and $85.3 \pm 6 \text{ kcal. mole}^{-1}$, respectively. A. L. Compagnon and P. O. Ellison, *J. Chem. Phys.* 32, 1132 (1960), and P. C. H. Jordan and H. C. Lonquet-Higgins, *Mol. Phys.* 5, 121 (1962) have calculated theoretically the dissociation energy by a semi-empirical method and obtained $83.3 \text{ kcal. mole}^{-1}$ and $81.2 \text{ kcal. mole}^{-1}$, respectively. These results are in good agreement. G. Herzberg, "Spectra of Diatomic Molecules", 2nd Ed., D. Van Nostrand Company, New York, 1950, has estimated the dissociation energy $D_0(\text{NH}, g) = 3.8 \text{ e.v.}$ ($87.6 \text{ kcal. mole}^{-1}$) based on the average of two earlier theoretical calculations by R. S. Mulliken, ($D_0 = 4.2 \text{ e.v.}$), *Rev. Mod. Phys.* 4, 1 (1932) and O. King ($D_0 = 3.4 \text{ e.v.}$), *J. Chem. Phys.* 5, 378 (1938). A. G. Gaydon, "Dissociation Energies", 2nd Ed. Chapman & Hall Ltd, London, 1953, favored G. Glockler's estimation $D_0 = 86.3 \text{ kcal. mole}^{-1}$ which was based upon the comparison of force constants and D values of related hydrides (i.e. CH, OH and PH).

Heat Capacity & Entropy.

The rotational constants B_e and α_e were obtained from R. N. Dixon, *Can. J. Phys.* 37, 1171 (1959). The vibrational constants ω_e and $\omega_e x_e$ were calculated from Dixon's data: $B_e = 16.6684 \text{ cm.}^{-1}$, $D_e = 16.85 \times 10^{-4} \text{ cm.}^{-1}$ and $\omega_e = 3125.6 \text{ cm.}^{-1}$ by the relation $D_e = 4 B_e^2 / \omega_e^2$ and $\omega_e = \omega_e - 2 \omega_e x_e$.

D. E. Milligan and M. E. Jacox, *J. Chem. Phys.* 41, 2838 (1964) have observed from the spectrum of NH the vibrational fundamental $\omega = 3135 \pm 2 \text{ cm.}^{-1}$ in Ar and N_2 matrices. K. Rosengren and O. C. Flament, *J. Chem. Phys.* 43, 507 (1965) also reported $\omega = 3122.2 \pm 0.6 \text{ cm.}^{-1}$ in N_2 matrix and $\omega = 3131.6 \pm 0.4 \text{ cm.}^{-1}$ in Ar matrix.

1570 (1)

1110 (1)

Bond Distance: H-N = 1.020 ± 0.02 Å N=O = 1.239 ± 0.005 Å

Bond Angle: H-N-O = 114° 25' ± 2°

Product of the Moments of Inertia: I_AI_BI_C = 5.939 X 10⁻¹¹⁸ g.³ cm.⁶

Heat of Formation

ΔH_f⁰ = 23.15 for HNO(g) was calculated from D(H-NO) = 48.6 kcal. mole⁻¹ at 0°K. reported by M. J. Y. Clement and D. A. Ramsay, Can. J. Phys. 39, 205 (1961).

Heat Capacity and Entropy

Vibrational frequencies were assigned by J. L. Bancroft, J. M. Hollas and D. A. Ramsay, Can. J. Phys. 40, 322 (1962) and H. Brown and G. Pinetel, J. Chem. Phys. 29, 883 (1958). Bond distances and bond angles were taken from J. L. Bancroft, J. M. Hollas, and D. A. Ramsay, loc. cit. The molecular constants given by P. W. Dalby, Can. J. Phys. 36, 1336 (1958) were: r(N=O) = 1.2116 Å, r(N-H) = 1.0628 Å, and \angle HNO = 108.6°. The three principal moments of inertia are: 1.262 X 10⁻⁴⁰, 2.1067 X 10⁻⁵⁹, and 2.2330 X 10⁻⁵⁹ g. cm.²

Point Group C_{2v} $\Delta H_f^0 = -16.85 \pm 0.32$ kcal. mole⁻¹ $\Delta H_f^0 = -16.85 \pm 0.32$ kcal. mole⁻¹

Ground State Multiplicity = [1]

Vibrational Frequencies and Degeneracies

 ω, cm^{-1} ω, cm^{-1}

Bond Distances: O-N = 1.20 Å N-O = 1.46 Å O-H = 0.98 Å

Bond Angle: O-N-O = 114° N-O-H = 103°

Product of the Moments of Inertia: $I_{AB}^2 = 5.5074 \times 10^{-116} \text{ g}^3 \text{ cm}^6$

Heat of Formation.

P. G. Ashmore and B. J. Tyler, J. Chem. Soc. 1017 (1961) reported ΔH_f^0 298.15 = -9.06 ± 0.32 kcal. mole⁻¹ for the reaction: $\text{NO(g)} + \text{NO}_2(\text{g}) + \text{H}_2\text{O(g)} \rightleftharpoons 2\text{HNO}_2(\text{g})$, yielding ΔH_f^0 298.15 = -18.57 ± 0.20 kcal. mole⁻¹ for $\text{HNO}_2(\text{g})$. L. H. Jones, R. M. Badger and G. E. Moore, J. Chem. Phys., 19, 1599 (1951) estimated the difference in energy of cis- and trans- $\text{HNO}_2(\text{g})$ to be 506 ± 250 cal. mole⁻¹. Hence the value of ΔH_f^0 298.15 for cis- $\text{HNO}_2(\text{g})$ was calculated.

The heat of reaction and the equilibrium constants for the formation of $\text{HNO}_2(\text{g})$ have been calculated by M. M. Karavayev and G. A. Skvortsov, Russ. J. Phys. Chem. 36, 566 (1962). The value of ΔH_f^0 298.15 reported is -18.9 kcal. mole⁻¹. However, based on the heat of formation of liquid HNO_2 , F. G. Ashmore and B. P. Levitt, Trans. Faraday Soc., 53, 945 (1957) give ΔH_f^0 = -13.7 kcal. mole⁻¹. The corresponding value reported by W. A. Rosser and H. Wise, J. Chem. Phys., 28, 571 (1957) is -20.0 kcal. mole⁻¹, based on the experimental data of L. G. Wayne and D. M. Vost, J. Chem. Phys., 19, 41 (1951), and the entropy of the equilibrium mixture of the trans- and cis- $\text{HNO}_2(\text{g})$ calculated by L. H. Jones, R. M. Badger and G. E. Moore, loc. cit.

Heat Capacity and Entropy.

Vibrational frequencies, bond distances, and bond angles were obtained from L. Dor and P. Tarte, Bull. Soc. Roy. Sci., LG. 478 (1951) and L. H. Jones, R. M. Badger and G. E. Moore, loc. cit. The three principal moments of inertia are: 1.0277 × 10⁻³⁹, 6.8242 × 10⁻³⁹, and 7.8520 × 10⁻³⁹ g. cm².

Bond Distance: O-N = 1.206 ± 0.005 Å N-O = 1.405 ± 0.005 Å O-H = [0.96] Å

Bond Angle: O-N-O = 130° ± 20° N-O-H = 102° ± 30°

Product of the Moments of Inertia: I_AI_BI_C = 6.08612 X 10⁻¹¹⁵ g.³ cm.⁶

Heat of Formation.

ΔH°_f 298.15 was taken from National Bureau of Standards Report 7437, January 1, 1962. Equilibria involving HNO₃ were measured by E. J. Jones, J. Am. Chem. Soc. 85, 2274 (1943), G. Peck, J. Am. Chem. Soc. 76, 5858 (1954) and H. E. Abel, H. Schmid and M. Stein-Wien, Z. Elektrochem. 55, 692 (1950), yielding ΔH°_f = -32.06, -32.02, and -32.09 kcal. mole⁻¹, respectively. G. Becker and W. A. Roth, Z. Elektrochem. 40, 835 (1934) and J. Thomsen, "Thermochemische Untersuchungen," Barth, Leipzig, 1882-1886, measured the heat of neutralization of HNO₃(aq.) with NH₃, combining these values with the data for NH₃NO₃ yields ΔH°_f = -32.27 and -32.07 kcal. M. Berthelot, "Sur la Force des Matieres Explosives," 3rd. ed., Paris, 1883, measured the heat of reaction of N₂O₄(g) and Cl₂(g), obtaining ΔH°_f = -32.10 kcal. mole⁻¹. The value of ΔH°_f 298.15 reported by M. R. Forsythe and W. P. Giauque, J. Am. Chem. Soc. 64, 48 (1942) was -31.994 kcal. mole⁻¹. The value adopted is the weighted average of these six values.

Heat Capacity and Entropy.

Vibrational frequencies were obtained from A. Palm and M. Kilpatrick, J. Chem. Phys. 23, 1562 (1955). Bond distances and bond angles were taken from D. J. Millen and J. R. Morton, J. Chem. Soc., 1523 (1960). The basic parameters of HNO₃(g) reported by P. A. Aikman, L. V. Vilkey and V. Y. Rosolovskii, Zhur. Strukt. Khim. 1, 1 (1960) were: r(N-O) = 1.22 ± 0.01 Å; r(N-O) = 1.40 ± 0.01 Å and ∠ O-N-O = 135° ± 2.5°. Forsythe and Giauque, loc. cit. have calculated the absolute entropy of pure nitric acid (g) from calorimetric data. The value obtained was S°_{298.15} = 63.62 cal. deg.⁻¹ mole⁻¹. The entropy of nitric acid vapor at 298.1°K. has also been computed by H. Cohn, C. K. Ingold, and H. G. Poole, J. Chem. Soc. 4272 (1952) to be 63.70 cal. deg.⁻¹ mole⁻¹. The three principal moments of inertia are: 6.4299 X 10⁻³⁹, 7.0314 X 10⁻³⁹, and 1.3461 X 10⁻³⁸ g. cm.²

Heat of Formation.

ΔH_f^o 298.15 was obtained from S. R. Gunn and L. G. Green, *J. Am. Chem. Soc.* **80**, 4782 (1958). The value of ΔH_f^o 298.15 reported by C. E. Messer, L. G. Fessolino and C. E. Thalmayer, *J. Am. Chem. Soc.* **77**, 4524 (1955) was -13.60 ± 0.27 kcal. mole⁻¹ which is in excellent agreement with the value given by S. R. Gunn and L. G. Green, loc. cit. The results of the previous investigations were also reviewed by C. E. Messer, et al., loc. cit.

Heat Capacity and Entropy.

C_p below 350°K were measured by E. F. Westrum, et al., University of Michigan, Ann Arbor, Michigan, private communication, May 18, 1960. C_p above 350°K were estimated by comparison with those for LiH(c). C_p 59.94 ~ 91.84°K., were also measured by E. V. Sayre and J. J. Beaver, *J. Chem. Phys.* **18**, 584 (1950). S° at 100°, 200°, and 298.15° were taken from E. F. Westrum, et al., loc. cit., using S°₁₀(extrap.) = 0.008 cal. deg.⁻¹ mole⁻¹.

Temperature of Decomposition.

T_d was estimated from the value of ΔF° in the table. The value of T_d given by D. M. Banus, J. J. McSharry and E. A. Sullivan, *J. Am. Chem. Soc.* **77**, 2007 (1955) was 940°K. It was assumed that NaH would behave similarly to LiH and that decomposition pressures would be purity dependent, and this would produce apparently high T_d's.

Heat of Formation.

The standard enthalpy of formation, ΔH_f° 298 (NaOH, c) = -101.90 ± 0.1 kcal. mole⁻¹, was calculated from the heat of solution of sodium hydroxide (c) and the heat of sodium metal hydrolysis and the appropriate auxiliary data.

N. A. Peshtetnikov¹ has measured the heat of solution NaOH(c) → NaOH(aq) as -10.445 ± 0.015 kcal. mole⁻¹ at 298.15°K. by solution calorimetry. Using the auxiliary heat of dilution reported by V. B. Parker², the selected heat of solution of sodium hydroxide (c) at infinite dilution is -10.555 kcal. mole⁻¹. Also L. E. Murch and W. F. Glaque¹¹ measured calorimetrically the heat of solution of solid samples of NaOH·nH₂O in the range from n = 0.1 to 1.0. When extrapolated to n = 0 and infinite dilution², this result yields the heat of solution of NaOH(c) at infinite dilution, ΔH_s° 298 = -10.636 kcal. mole⁻¹, which is in good agreement with the value selected.

The heat of sodium metal hydrolysis, ΔH_f° 298, has been measured in the solution calorimeter by the following investigators. Na(c) + H₂O(l) → NaOH(aq) + 1/2 H₂(g) ΔH_f° 298

Source	Number of Moles of H ₂ O	ΔH_f° 298 kcal. mole ⁻¹	ΔH_f° 298 (NaOH(aq), c) kcal. mole ⁻¹	ΔH_f° 298 (NaOH, c) kcal. mole ⁻¹
Gunn et al. ³	1000	-44.047 ± 0.008	-112.446	-101.899
Messer et al. ⁴	CO	-44.215 ± 0.20	-112.530	-101.975
Ketchen et al. ⁵	CO	-44.054 ± 0.20	-112.369	-101.814

The values of ΔH_f° 298 (NaOH(aq), c) were calculated from the heats of reaction ΔH_f° 298 using the ΔH_f° 298 (H₂O, l) = -68.315 kcal. mole⁻¹.⁶ Combination of the selected heat of solution of NaOH(c) at infinite dilution with the heat of formation of NaOH(aq) gives the heat of formation of NaOH(c) in the last column of the table. A weighted average of these three measurements has been taken for the selected heat of formation of sodium hydroxide (c).

The earlier investigations have been reviewed by F. R. Bichowsky and F. D. Rossini⁹, and C. E. Messer et al.⁴, and these earlier reported data are not adopted in the tabulation.

Heat Capacity and Entropy.

L. E. Murch and W. F. Glaque¹¹ have measured low temperature heat capacities of NaOH·0.04014 H₂O and NaOH·0.97776 H₂O from 15° to 320°K. and calculated the values of C_p for the pure phase of NaOH(c). T. B. Douglas and J. L. Dever⁹ have measured the enthalpy changes from 273° to 973°K. in the drop calorimeter and derived the heat capacities. The low temperature and the high temperature heat capacities were joined smoothly by Murch and Glaque, and the smooth values were adopted in the tabulation. Low temperature heat capacities from 60° to 300°K. have also been measured by J. C. R. Kelly and P. E. Snyder⁷, whose data are in good agreement with those reported by Murch and Glaque. M. M. Popov and D. M. Ginzburg¹⁰ have determined the heat capacities of NaOH(c) in the temperature range from 298° to 577°K. from the enthalpy measurements by drop calorimetry. The reported $H_{500}^\circ - H_{298}^\circ$ = 3.112 kcal. mole⁻¹ is in good agreement with the tabulated value.

Transition and Melting Data.

The adopted heat of transition and the transition temperature, and the adopted heat of melting and the melting point were obtained from Douglas and Dever,⁹ Popov and Ginzburg,¹⁰ reported the heat of transition ΔH_{tr}° = 1.930 kcal. mole⁻¹ at 576.8°K. and the heat of melting ΔH_m° = 1.629 kcal. mole⁻¹ at 595.16°K.

Heat of Sublimation.

See NaOH(g) table for details.

$$S_{298.15}^{\circ} = 17.727 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^{\circ} 298.15 = -89.988 \text{ kcal. mole}^{-1}$$

$$T_m = 592.25^{\circ}\text{K.}$$

$$\Delta H_m^{\circ} = 1.519 \text{ kcal. mole}^{-1}$$

$$T_b(\text{monomeric gas}) = 1682.7^{\circ}\text{K.}$$

$$\Delta H_v^{\circ}(\text{to monomer}) = 37.9 \text{ kcal. mole}^{-1}$$

Heat of Formation.

The heat of formation of NaOH(l) at 298°K. was obtained from that of the crystal by adding ΔH_m° and the difference between $H_{592.25}^{\circ}$ - $H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

The selected heat capacities in the temperature range from 592.3° to 1000°K. were obtained from the enthalpy measurements of sodium hydroxide (l) in the drop calorimeter by T. B. Douglas and J. L. Dever¹. The heat capacities below the melting point and above 1000°K. were extrapolated from the selected heat capacity curve.

Douglas and Dever¹ have also compared their heat capacity values with those from W. D. Fowles and G. C. Blalock² who have applied the same drop method to determine the heat capacities of NaOH(l). Both results are in reasonable agreement. M. M. Popov and G. M. Ginzburg³ applying the same technique obtained different values of heat capacity. The smoothed enthalpy data reported by Ginzburg⁴ are 200 to 500 cal. mole⁻¹ smaller than the tabulated values at the temperature range from 700° to 1000°K.

The entropy ($S_{298}^{\circ} = 17.65 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$) was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See NaOH(c) table for details.

Vaporization Data.

The boiling point 1682.7°K. was calculated as the temperature at which the free energies of formation (ΔF_f°) for both NaOH(l) and NaOH(g) are equal. The difference in the heats of formation (ΔH_f°) of NaOH(l) and NaOH(g) at the boiling point is the heat of vaporization. If $\text{Na}_2(\text{OH})_2(\text{g})$ is also considered as a minor component in the vapor mixture (approximately 6% of total vapor pressure at the boiling point) the calculated boiling point is 1653°K. (see NaOH(g) table for details).

H. von Wartenberg and P. Albrecht, Z. Elektrochem. 27, 162 (1921), have studied the vapor pressures of liquid NaOH and reported the boiling point as 1661°K.

Heat of Formation.

R. C. Schoonmaker and R. P. Porter, J. Chem. Phys. **28**, 454 (1958), have found in their mass-spectrometric studies that the NaOH(l) vaporizes mainly as gaseous dimer in the temperature range from 575° to 723°K. They have also calculated by the slope method the heat of dimerization, $\Delta H_d^\circ = -54 \pm 5 \text{ kcal. mole}^{-1}$, for $2\text{NaOH(g)} = \text{Na}_2\text{(OH)}_2\text{(g)}$ and the heat of sublimation, $\Delta H_s^\circ = 46.3 \pm 3 \text{ kcal. mole}^{-1}$, for $\text{NaOH(c)} = \text{NaOH(g)}$. The second law values were determined using ion intensity ratios, however, a third law calculation using a single data point converted by the authors to absolute pressure (J. Phys. Chem. **62**, 486 (1958)) yields $\Delta H_d^\circ = -51.6 \text{ kcal. mole}^{-1}$, $\Delta H_s^\circ = 49.5 \text{ kcal. mole}^{-1}$ and $\Delta H_f^\circ = 49.5 \text{ kcal. mole}^{-1}$ (to dimer) = 41.1 kcal. mole⁻¹, which are in agreement within the limit of uncertainty. Later, Porter and Schoonmaker, J. Chem. Phys. **31**, 830 (1959), found the activity of molten alkali hydroxide had been reduced in the presence of MgO in their sample container, and the uncertainty in the heat of sublimation might be $\pm 5 \text{ kcal. mole}^{-1}$, but the heat of dimerization should not be seriously affected because it was calculated from slopes of both species. In order to have good agreement between the calculated total pressures of monomer and dimer of sodium hydroxide (g) and the observed vapor pressures by H. von Wartenberg and P. Albrecht, Z. Elektrochem. **27**, 162 (1921), the heat of dimerization and the heat of sublimation have been so chosen as $\Delta H_d^\circ = -54 \text{ kcal. mole}^{-1}$ and $\Delta H_s^\circ = 49.5 \text{ kcal. mole}^{-1}$ (to monomer) = 51.5 kcal. mole⁻¹, respectively, which are still within the limit of Porter and Schoonmaker's data. The calculated boiling point is 1653°K. which is in good agreement with 1661 ± 20°K. reported by Wartenberg and Albrecht, loc. cit. The heats of formation were calculated from the selected heat of dimerization and heat of sublimation as $\Delta H_f^\circ = -50.4 \text{ kcal. mole}^{-1}$ and $\Delta H_f^\circ = -154.8 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The bent molecular configuration with the bond angle of 110° was proposed by S. H. Bauer, R. M. Diner and P. P. Porter, J. Chem. Phys. **29**, 931 (1958). The bond distance Na-O was estimated from that in H₂O(g). The bond distance Na-O was estimated by adding the bond length difference (0.04 Å) between H-OH(g) and H-F(g) to the bond distance Na-F(g) (1.9259 Å) which has been accurately measured by R. K. Bauer and H. Lew, Can. J. Phys. **41**, 1461 (1963). The Na-O stretching frequency was obtained from L. H. Spinar and J. L. Margrave, Spectrochim. Acta **12**, 244 (1956), in the infrared spectroscopic studies. The O-H stretching and the bending frequencies were estimated by comparison with H-OH, D-OH and T-OH which indicate rigid convergence to a constant as a heavier atom is attached. The three principal moments of inertia are $I_A = [0.1252] \times 10^{-59}$, $I_B = [6.449] \times 10^{-59}$ and $I_C = [6.5742] \times 10^{-59} \text{ g. cm.}^2$.

 $B_e = 18.871 \text{ cm.}^{-1}$

Heat of Formation.

P. Oray, Trans. Farad. Soc. 55, 408 (1959) has summarized the determinations of the heat of formation of OH and concludes that the short extrapolation by Barrow, Arkiv. Fysik, 11, 281 (1956) of the $B(\sum^+)$ $\rightarrow A(\sum^+)$ system gives the most reliable result. The value of $D_0 = 101.33 \text{ kcal. mole}^{-1}$ was adopted and leads to a heat of formation of $9.432 \text{ kcal. mole}^{-1}$. A recent determination of the dissociation energy from measurements of the concentration of the radicals in water oxygen mixtures by A. P. Furmal and A. V. Prost, Vestn. Mosk. Univ., Ser. II Khim. 16, 25 (1961) gives $\Delta H_f^{\circ}(\text{OH}) = 102.8 \pm 0.8 \text{ kcal. mole}^{-1}$ in good agreement with the adopted value. Also V. A. Medvedev, V. V. Korobov and V. F. Baibuz, Zhur. Fiz. Khim. 33, 58 (1959) reported a heat of dissociation of $102.2 \pm 1 \text{ kcal. mole}^{-1}$ from dissociation of water in a spherical bomb.

Heat Capacity and Entropy.

The molecular constants were all given by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. New York, 1950. This calculation gives values in excellent agreement with L. Hear, A. S. Friedman and C. W. Beckett, National Bureau of Standards Monograph No. 20, May 1961. The agreement with the higher order correction calculations of H. L. Johnston, J. Belzer and L. Savodnik, TR 316-5, Ohio State University, available as ATI 139 987, is good between 298 and 4000°K. This earlier work uses different constants and also a different value of the ground state splitting constant, but at 6000°K. the entropy difference is still less than 0.25%.

HO⁺

HYDROXYL UNIPOSITIVE ION (OH⁺) (IDEAL GAS) MOL. WT. = 17.0068

Ground State Configuration $3 \sum^-$
 $\Delta H_f^o = 313.3 \pm 2.5 \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = 43.657 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^o 298.15 = 314.8 \pm 2.5 \text{ kcal. mole}^{-1}$

Electronic Levels and Multiplicities

$\epsilon_i, \text{ cm.}^{-1}$ g_i
 0 3
 $\omega_e x_e = [74]$ $\sigma^+ = 1$
 $B_e = 16.795 \text{ cm.}^{-1}$ $\alpha_e = 0.732 \text{ cm.}^{-1}$ $r_e = 1.0289 \text{ \AA}$

Heat of Formation.

The ionization potential of hydroxyl has been determined by M. M. Mann, A. Rustulid and J. T. Tate, Phys. Rev. 58, 340 (1940) from electron impact data on water vapor, as 13.6 e.v. S. N. Poner and R. L. Hudson, J. Chem. Phys. 25, 602 (1956) have measured the appearance potential of OH⁺ from OH as $13.18 \pm 0.1 \text{ e.v.}$ (303.98 kcal.). This value was the one adopted to obtain the heat of formation of OH⁺(g) from that of OH(g) at 0°K.

Heat Capacity and Entropy.

The molecular constants, with the exception of $\omega_e x_e$, were all given by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. New York, 1950. The value of $\omega_e x_e$ was estimated by analogy with OH(g) and other diatomic hydrides.
 The value of $H_{298}^o - H_{298}^o$ at 0°K. is -2.06 kcal. mole⁻¹.

$B_e = 18.87 \text{ cm.}^{-1}$

$\alpha_e = [0.65] \text{ cm.}^{-1}$

Heat of Formation

L. M. Branscomb, Joint Institute for Laboratory Astrophysics Report No. 62, Feb. 1st, 1966 has deduced an electron affinity of OH of $1.83 \pm 0.04 \text{ e.v.}$ ($42.2 \pm 0.9 \text{ kcal.}$) from the photodetachment spectrum of OH⁻(g). The vibrational state was deduced to be the ground state since no other absorption sequences could be detected by a thorough search. F. M. Page, Faraday Soc. Discussions 19, 87 (1955) has reviewed the methods and results of earlier determinations of the electron affinity of OH(g) and concludes that it is $65 \pm 1 \text{ kcal.}$ However he does state that it is not generally known whether the flame systems chiefly investigated are in thermodynamic equilibrium. In a later paper F. M. Page and T. M. Sugden, Trans. Faraday Soc. 53, 1092 (1957) conclude that much higher concentrations of radicals are obtained in flames than predicted thermodynamically. However for certain systems at lower temperatures they estimate only a factor of 3 increase in concentration and thus calculate the electron affinity as $61 \text{ kcal. mole}^{-1}$. The value reported by Branscomb, loc. cit. is adopted here.

Heat Capacity and Entropy

Branscomb loc. cit. has used his photodetachment spectra to obtain values of ω_e , B_e and r_e for OH⁻(g) which are remarkably similar to those for OH(g). The values of $\omega_e x_e$ and α_e were estimated by comparison with OH(g) and other hydrides. The ground state configuration was assumed to be that of HP(g) with which it is isoelectronic.

The value of H_{298}^o at 0°K. is $-2.057 \text{ kcal. mole}^{-1}$.

HYDROPEROXYL (HO₂)

(IDEAL GAS)

Point Group C₁
ΔH°_f 0 = 6 ± 2 kcal. mole⁻¹
ΔH°_f 298.15 = 54.393 cal. deg.⁻¹ mole⁻¹
ΔH°_f 298.15 = 5 ± 2 kcal. mole⁻¹
Ground State Quantum Weight = [2]

Vibrational Frequencies and Degeneracies

ω, cm. ⁻¹	g _i
1389.4	(1)
1101	(1)
5414	(1)

Bond length: H-O = [0.958] Å
Bond angle: HOO = [120°]
Product of the Moments of Inertia: I_AI_BI_C = [0.6424] X 10⁻¹¹⁷ g.³ cm.³
σ = 1

Heat of Formation.

S. N. Foner and R. L. Hudson, J. Chem. Phys. 36, 2681 (1962) have determined the ionization potential of HO₂ and the appearance potential of HO₂⁺ from H₂O₂. Using the ΔH°_f of H₂O₂(g) determined by P. A. Giguere and I. D. Liu, J. Am. Chem. Soc. 77, 6477 (1955), they calculate ΔH°_f 0 HO₂ = 5.7 ± 2 kcal. mole⁻¹.

Heat Capacity and Entropy.

The point group must be C₁ as the two oxygen atoms have been shown to be non-equivalent, from the increased number of infra-red bands obtained when using O₂¹⁸ enriched with 28% of O₂¹⁸, by D. E. Milligan and M. E. Jacox, J. Chem. Phys. 39, 2027 (1963). They also reported the three frequencies given above in the infra-red spectrum of the matrix isolated HO₂ radical. The bond lengths were taken equal to those estimated by M. E. Boyd, J. Chem. Phys. 37, 1317 (1962), the angle was that recommended by Milligan and Jacox, loc. cit. Boyd's conclusion that the lowest energy configuration should be an isosceles triangle could not be accepted in view of the nonequivalence of the oxygen atoms. The electronic ground state was taken as 2A'' as predicted by A. D. Walsh, J. Chem. Soc. London, 2288 (1953).

PHOSPHORUS MONOHYDRIDE (PH) (IDEAL GAS) GFW = 31.98177

Ground State Configuration 3s²

S_{298.15} = 46.9 gibbs/mol

Electronic Levels and Quantum Weights

E _i , cm ⁻¹	g _i	E _i , cm ⁻¹	g _i
0	3	29560	6
[7650]	2	[38110]	2
[15150]	1	[57490]	1

ω_e = 2380 cm⁻¹ ω_eX_e = [55] cm⁻¹ σ = 1

B_e = 8.412 cm⁻¹

r_e = 1.43 Å

Heat of Formation

Jordan (1) estimated the dissociation energy (D₀) of PH(g) as 70.44 kcal/mol using a semiempirical theoretical method. The corresponding value for the heat of formation (ΔH_{298.15}^o) is 60.6 ± 8 kcal/mol.

Heat Capacity and Entropy

Jordan (1) predicted five electronic levels (X²Σ, A²Δ, B²Π, D²Π, E²Σ) based on the reported value (2) of 29560 cm⁻¹ for the C²Π level (this level is designated A²Π by Herzberg (2)). Several qualitative spectroscopic investigations of PH(g) have been reported and are in general accord with the predictions of Jordan (1). Isaha and Pearce (3) reported the values of the rotational constant B_e and the fundamental vibrational frequency ω_e. The value of ω_e is calculated from the Morse potential function. The bond distance is calculated from B_e. The value of the anharmonic vibrational term ω_eX_e is estimated from the relation ω_eX_e = ω_e²/(4D₀ + 2ω_e).

Lead Monohydride (PbH) (Ideal Gas)

Mol. Wt. = 208.22

 $\Delta H_f^\circ 298.15 = 56.5 \pm 4.6$ kcal. mole⁻¹ $S^\circ 298.15 = 52.737$ cal. deg.⁻¹ mole⁻¹Ground State Configuration $2\pi_{1/2}^2$

Electronic Levels and Multiplicities

 $\epsilon, \text{ cm.}^{-1}$ g_i

0 2

[8000]

2

 $\omega_e = 1564.1 \text{ cm.}^{-1}$ $\omega_e x_e = 29.75 \text{ cm.}^{-1}$ $B_e = 4.971 \text{ cm.}^{-1}$ $\alpha_e = 0.144 \text{ cm.}^{-1}$ $\sigma = 1$

Heat of Formation. $\Delta H_f^\circ 298.15$ was calculated from the dissociation energy of PbH(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration and spectroscopic data were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York (1950). Electronic levels and multiplicity were estimated by comparison with those for PbF(g).

SULFUR MONOHYDRIDE (SH)

(IDEAL GAS)

GFW = 33.07197

Ground State Configuration 2π

$$\Delta H_{\text{O}}^{\circ} = 34.4 \pm 4 \text{ kcal/mol}$$

$$S_{298.15}^{\circ} = 46.73 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = 34.6 \pm 4 \text{ kcal/mol}$$

Electronic Levels and Quantum Weights

$\frac{E_i, \text{cm}^{-1}}{0}$	$\frac{g_i}{2}$	$\frac{E_i, \text{cm}^{-1}}{59836}$	$\frac{g_i}{2}$
376.9	2	[63850]	4
30682.4	2	75000	18
$\omega_e = 2702 \text{ cm}^{-1}$	$\omega_e x_e = 60 \text{ cm}^{-1}$	$\sigma = 1$	
$B_e = 9.611 \text{ cm}^{-1}$	$\alpha_e = [0.3] \text{ cm}^{-1}$	$r_e = 1.3397 \text{ \AA}$	

Heat of Formation

Mackie (1) estimated ΔH_{298}° of SH(g) as $34.5 \pm 4 \text{ kcal/mol}$, this value being an average of three independent determinations.

He obtained these three values by the following methods: (A) He calculated ΔH_{298}° of SH(g) as $34.9 \pm 4.5 \text{ kcal/mol}$ from ΔH_{298}° of thiobenzyl alcohol (g), ΔH_{298}° of the benzyl radical (g) and the heat of dissociation (D_0°) of thiobenzyl alcohol reported by Sehon and Darwent (2). (B) A value of $35.2 \pm 4.5 \text{ kcal/mol}$ was calculated from ΔH_{298}° of C_2H_5 (g), ΔH_{298}° of C_2H_5SH (g) and the appearance potential of C_2H_5 reported by Franklin and Lumpkin (3). (C) He calculated that ΔH_{298}° of SH(g) is $33.7 \pm 3 \text{ kcal/mol}$ from ΔH_{298}° of H_2S (g) and the mass spectrographic data for the reactions $H_2S = SH^+ + H + e^-$ and $SH = SH^+ + e^-$ reported by Palmer and Lossing (4). The adopted value of $34.5 \pm 4 \text{ kcal/mol}$ compares with a value of 34.9 kcal/mol obtained from a linear Birge-Sponer extrapolation of the potential function.

Heat Capacity and Entropy

The high resolution spectra of SH(g) have been studied by Ramsay (5) and Johns and Ramsay (6) in the near UV and by Morrow (7) in the vacuum UV. The energy levels of the doublet ground state and of the first excited state ($^2\Sigma$) were reported by Ramsay (5). Six of the seven higher excited levels ($8^2\Sigma$, $9^2\Sigma$, $10^2\Sigma$, $11^2\Sigma$, $12^2\Sigma$, $13^2\Sigma$) were reported by Morrow (7), the last five of which are shown as an average of 75000 cm^{-1} . The remaining electronic level ($14^2\Sigma$) is estimated by analogy with the electronic levels of SD(g) reported by Morrow (7).

Ramsay (5) reported the following rotational and vibrational constants: $B_0 = 9.461 \text{ cm}^{-1}$, $\omega_e = 2702 \text{ cm}^{-1}$, and $\omega_e x_e = 60 \text{ cm}^{-1}$. The value of α_e is calculated from the Morse potential function. The rotational constant B_e is calculated from $B_e = B_0 + \alpha_e/2$. The bond distance is calculated from B_e .

Heat of Formation		
-------------------	--	--

Verma (1) has derived an upper limit to the dissociation energy of 24680 cm ⁻¹ (70.56 kcal) from predissociation in the B ₂ ⁺ state. With JANAF values for Si(g) and H(g) this yields $\Delta H_f^\circ(\text{SiH}_2, g) \geq 87.73 \text{ kcal/mol}$. We adopt a value of $\Delta H_f^\circ(\text{SiH}_2, g) = 90 \pm 2 \text{ kcal/mol}$, assuming that the predissociation has a 2 kcal barrier similar to that in the predissociation of the A ¹ Π state of AlH. Hildenbrand (5) has applied an ionic-covalent correction to the linear Birge-Sponer extrapolation of the ground state dissociation energy and obtains D ₀ (SiH ₂ , g) = 70 kcal in excellent agreement with the predissociation value.		
-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--	--

Heat Capacity and Entropy		
---------------------------	--	--

The observed electronic levels and rotational and vibrational constants are from Herzberg et al. (2), Klymning and Lindgren (3), and Verma (1). The estimated levels are from the calculations of Jordan (4). The upper states are all assumed to have ground state molecular constants. This approximation introduces negligible error when the first state is as high as 21000 cm ⁻¹ and has the same multiplicity as the ground state.

June 30, 1963

Ground State Configuration [2T] $\Delta H_f^o = [123.7] \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = [51.638] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^o_{298.15} = [123.4] \text{ kcal. mole}^{-1}$

Electronic Levels and Multiplicities

E_1	E_1
0	[4]
$\omega_e X_e = [19] \text{ cm.}^{-1}$	$\epsilon = 1$
$\omega_e = [1400] \text{ cm.}^{-1}$	$r_e = [1.821] \text{ \AA}$
$B_e = [5.1] \text{ cm.}^{-1}$	$\alpha_e = [0.09] \text{ cm.}^{-1}$

Heat of Formation.

ΔH_f^o was estimated as 123.7 kcal. mole⁻¹ by J. S. Gordon, AstroSystems International, Livingston, New Jersey, private communication, January 10, 1963. $\Delta H_f^o_{298.15}$ was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. r_e was calculated from the relationship $r_e = (16.858778/\mu B_e)^{1/2} \text{ \AA}$.

Bond Distance: K-O = $[2.43] \text{ \AA}$ O-H = $[0.98] \text{ \AA}$
 Bond Angle: K-O-K = $[90^\circ]$ K-O-H = $[110^\circ]$
 Products of the Moments of Inertia: $I_A I_B I_C = [3.7587] \times 10^{-113} \text{ g.}^3 \text{ cm.}^6$
 $\sigma = 2$

Heat of Formation.

See KOH(g) table for details.

Heat Capacity and Entropy.

S. H. Bauer, R. H. Diner and R. F. Porter, J. Chem. Phys. **29**, 991 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. F. Porter, J. Chem. Phys. **31**, 830 (1959), have suggested a square planar model without hydrogen bonding with alkali-oxygen bond distances 0.2 \AA larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meschl and W. A. Chupka, J. Chem. Phys. **33**, 533 (1960), have also postulated a model for $\text{Li}_2(\text{OH})_2(\text{g})$ which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the bond angle O-Li-O = 100° . The last one was adopted for the molecular configuration of $\text{K}_2(\text{OH})_2$, but the bond angle O-K-O was modified to 90° (i.e. a square planar configuration for potassium and oxygen atoms). The bond angle K-O-K in $\text{K}_2(\text{OH})_2(\text{g})$ was assumed to be 110° . The bond distance K-O in $\text{K}_2(\text{OH})_2(\text{g})$ was estimated 10% longer than that in KOH(g). The bond distance O-H was estimated to be the same in $\text{H}_2\text{O}(\text{g})$. The three principal moments of inertia are $I_A = [17.5202] \times 10^{-39}$, $I_B = [38.5534] \times 10^{-39}$ and $I_C = [55.6452] \times 10^{-39} \text{ g. cm.}^2$. The first six selected vibrational frequencies were taken to be equal to those for $\text{K}_2\text{P}_2(\text{g})$ (see $\text{K}_2\text{P}_2(\text{g})$ table), and the rest were O-H stretching and bending frequencies which have been suggested by Berkowitz et al., loc. cit.

Bond Distances: Li-O = [1.76] Å O-H = [0.96] Å

Bond Angles: Li-O-Li = [90]° Li-O-H = [110]°

Product of the Moments of Inertia: I_AI_BI_C = [4.56956] X 10⁻¹¹⁵ g.³ cm.⁶

Heat of Formation.

J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have studied the Li₂O(c)-H₂O(g) equilibrium by the mass-spectrometric method. Using the reported equilibrium constants in the temperature range from 1100° to 1450°K. the heat of reaction Li₂OH₂(g) → 2LiOH(g) at 298° has been calculated by the second law and the third law methods as 63.2 and 63.7 kcal. mole⁻¹, respectively. (The third law drift is 0.5 ± 1.5 e.u.) Combination of the third law value (ΔH_f^o 298 = 63.7 kcal. mole⁻¹) with the heat of formation of lithium hydroxide(g) (ΔH_f^o 298 = -58.8 kcal. mole⁻¹) gives the heat of formation of dimeric lithium hydroxide (g) (ΔH_f^o 298 = -181.4 kcal. mole⁻¹) which has been adopted in the tabulation.

J. B. Berkowitz-Matuck and A. Buchler, J. Phys. Chem. 67, 1386 (1963), have also studied the Li₂O(c)-H₂O(g) equilibrium by the transpiration method, and reported two equilibrium constants (K₁₀₉₅^o = 0.105 and K₁₄₄₅^o = 0.357) for the reaction Li₂O(c) + H₂O(g) → Li₂OH₂(g). Using the third law method, the heat of reaction has been calculated from the equilibrium constants as 12.7 kcal. mole⁻¹ at 298.15°K. The heat of formation of Li₂OH₂(g) can be derived as ΔH_f^o 298 = -186.2 ± 3.5 kcal. mole⁻¹ which is different from the adopted value of Berkowitz, Meschi and Chupka, loc. cit. Berkowitz-Matuck and Buchler attempted to explain the difference by inferring that the solid-gas equilibrium was not properly established in the measurement of Berkowitz, Meschi and Chupka, however, the absence of drift in the third law analysis does not support this conclusion.

Heat Capacity and Entropy.

S. H. Bauer, R. M. Diner and R. P. Porter, J. Chem. Phys. 29, 991 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. P. Porter, J. Chem. Phys. 31, 630 (1959), have suggested a square planar model without hydrogen bonding with alkali-oxygen bond distances 0.2 Å larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have also postulated a model for Li₂(OH)₂(g) which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the bond angle O-Li-O = 100°. The last one was adopted for the molecular configuration of Li₂(OH)₂(g), but the bond angle O-Li-O was modified to 90° (i.e. a square planar configuration for lithium and oxygen atoms). The bond angle Li-O-H in Li₂(OH)₂(g) was assumed to be 110°. The bond distance Li-O in Li₂(OH)₂(g) was estimated 10% longer than that in LiOH(g). The bond distance O-H was estimated to be the same in H₂O(g). The three principal moments of inertia are: I_A = [9.445] X 10⁻³⁹, I_B = [3.789] X 10⁻³⁹ and I_C = [12.6035] X 10⁻³⁹ g. cm.²

The first six selected vibrational frequencies were taken to be equal to those for Li₂P₂(g) (see Li₂P₂(g) table) and the rest were O-H stretching and bending frequencies.

MAGNESIUM DIHYDRIDE (MgH₂)

(CRYSTAL)

MOL. WT. = 26.336

ΔH_f^o = -16.3 ± 2.2 kcal. mole⁻¹
ΔH_f^o 298.15 = -18.2 ± 2.2 kcal. mole⁻¹
S_{298.15}^o = 7.43 ± 0.20 cal. deg.⁻¹ mole⁻¹
T_d = [560]°K.

Heat of Formation.

The heat of hydrolysis of MgH₂(c) was measured by G. C. Sinke and D. R. Stull, Thermal Laboratory, The Dow Chemical Company, private communication, July, 1956. The value of ΔH_f^o 298.15 was calculated to be -19.1 ± 2 kcal. mole⁻¹. From the decomposition pressure measurements for MgH₂(c) reported by P. H. Ellinger, et al., J. Am. Chem. Soc. 77, 2647 (1955) and J. F. Stampfer, Jr., C. E. Holley, Jr. and J. F. Suttle, J. Am. Chem. Soc. 82, 3504 (1960), the values of ΔH_f^o 298.15 for MgH₂(c) were found to be -17.9 ± 1.0 and -17.7 kcal. mole⁻¹, respectively. The value used was the average of these three.

Heat Capacity and Entropy.

The low temperature heat capacities (25-300°K.) was measured by G. C. Sinke and D. L. Hildenbrand, Thermal Laboratory, The Dow Chemical Company, private communication, February 1958. Above 300°K. the C_p values were estimated by comparison with those for MgF₂(c). S_{298.15} was obtained from G. C. Sinke and D. L. Hildenbrand, loc. cit., using S₂₅^o (extrap.) = 0.037 cal. deg.⁻¹ mole⁻¹.

Temperature of Decomposition.

T_d was estimated from the value of ΔF_f^o in the table.

MAGNESIUM DIHYDROXIDE (Mg(OH)₂)

(CRYSTAL)

OPW = 58.32674

S_{298.15} = 15.10 gibbs/molT_d = [541]°KΔH_f^o = -218.43 ± 0.5 kcal/molΔH_f^o_{298.15} = -221.0 ± 0.5 kcal/mol

Heat of Formation.

The adopted value is an average of -221.10 and -220.86 kcal/mol obtained from ΔH_f^o₂₉₈ = 9.08 and 8.84 kcal/mol for the dehydration reaction Mg(OH)₂(c) = MgO(c) + H₂O(l). The two values correspond to naturally occurring brucite and to synthetic Mg(OH)₂ prepared from MgO by hydration at 177°C under a steam pressure of about 9 atm. The enthalpies of reaction are derived from studies of Taylor and Wells on the heats of solution of various samples of Mg(OH)₂ and MgO in aqueous HCl. These studies show that the heat of dehydration is quite dependent on the nature of the MgO sample; e.g., values for synthetic Mg(OH)₂ vary monotonically from 9.79 to 8.84 kcal/mol for MgO ignited at temperatures from 450 to 1425°C, respectively. The authors ascribe this difference primarily to increase in particle size at the higher ignition temperatures. We have adopted the results at 1425°C, since they are reasonably consistent with the high temperature samples on which the JANAF heat of formation for MgO is based. The uncertainty is estimated as ± 0.5 kcal/mol.

Shomate and Huffman have confirmed the heat of solution of MgO (ignited at 1000°C) within about 0.3 kcal. Their value may be combined with the heat of solution for synthetic Mg(OH)₂, determined under similar conditions by Torgeson and Sahaana, to obtain ΔH_f^o = 8.85 kcal/mol for the dehydration reaction. At the other extreme, the heat of solution data of Glaue and Archibald lead to ΔH_f^o = 9.74 kcal/mol; however, this value corresponds to MgO ignited at 350°C. The MgO sample was microcrystalline and had significant excess O₂, as suggested by Glaue and Archibald and later confirmed by data of T. H. K. Barron et al., Proc. Roy. Soc. (London) A250, 70 (1959). Glaue and Archibald intentionally used the microcrystalline form which would be similar to the product in their decomposition pressure measurements (190 and 212°C). Thus, it is not surprising that third law analysis of their decomposition pressures yields essentially the same heat of formation as their solution data (see summary below). Decomposition data at higher pressures have been reported by H. S. Pyfe, Am. J. Sci. 255, 729 (1956); D. M. Roy and R. Roy, ibid. 255, 573 (1957); O. C. Kennedy, ibid. 254, 567 (1956); G. M. Zhabrova and B. M. Madenatski, J. Gen. Chem. USSR (Eng. Transl.) 23, 1129 (1954); and L. G. Berg and I. S. Rassonakaya, Dokl. Akad. Nauk SSSR 91, 865 (1951). These data do not significantly affect the heat of formation, however, because of uncertainties in the attainment of equilibrium and in reduction to standard state values.

Heat Capacity and Entropy.

Low temperature heat capacities are from the data (22-321°K) of Glaue and Archibald, loc. cit., who used a synthetic, microcrystalline sample prepared by reaction of KOH with aqueous MgCl₂ at 210°C. The entropy is derived from the heat capacities using S₂₉₈^o = 0.027 eu. Above 321°K the heat capacities are extrapolated graphically. Enthalpy data (393-667°K) reported by F. N. Lashchenko and D. I. Kompan'skii, Zh. Fizik. Khim. 9, 628 (1935), were stated to be based on a calorimeter temperature close to room temperature. Within this uncertainty and the experimental scatter of about ± 5%, the enthalpy data are consistent with the selected values.

Temperature of Decomposition.

T_d is calculated as the temperature at which ΔH_f^o = 0 for Mg(OH)₂(c) = MgO(c) + H₂O(g).

O-Mg-O = [180°]			
I _A I _B I _C = [95.6929] x 10 ⁻¹¹⁷ g cm			

Heat of Formation

Vapor densities of magnesium-bearing species over magnesium oxide were determined, using the transpiration method, by C. A. Alexander, J. S. Ogden and A. Levy, J. Chem. Phys. **33**, 3057 (1963). The MgO reacted with water vapor present in the carrier gas to form a gaseous product, presumably Mg(OH)₂. The authors eliminated MgOH (and other species requiring the formation of gaseous oxygen) as a likely product by holding constant the partial pressure of water but varying the ratio of oxygen and argon in the carrier gas. Experiments with different partial pressures of water indicated that each mole of water produced an equivalent number of moles of product in the vapor. This eliminates [Mg(OH)₂] as a possible product, but not, for example, (MgO)₂H₂O. Species of the latter type are quite unlikely with magnesium, so the reaction is considered to be MgO(c) + H₂O(g) = Mg(OH)₂(g). Equilibrium data (1653-2020°K) given graphically by Alexander et al. yield ΔH_f^o = 67.6 ± 1.9 kcal/mol by second law analysis and ΔH_f^o = 65.2 kcal/mol with a drift of -1.5 ± 1 eu by third law analysis.

Heat Capacity and Entropy

The infrared spectra of Mg(OH)₂(c) were observed in the region 365-3700 cm⁻¹ by C. Cabannes-Ott, Ann. Chim. (Paris) **5**, 903-60 (1960). The vibrational frequencies of the gas are estimated by comparison with those for Mg(OH)₂(c), H₂O(g), H₂O₂(g), MgO(g) and MgF₂(g), and are adjusted to give reasonable agreement between the second and third law heats of reaction. The bond distances are estimated by comparison with those of MgF₂(g), MgO(g) and H₂O(g). The O-Mg-O angle is assumed to be 180°, while the Mg-O-H angle is assumed to be the same as that in H₂O(g). The three principal moments of inertia are I_A = 2.713 x 10⁻⁴⁰, I_B = 18.6455 x 10⁻³⁹ and I_C = 18.9168 x 10⁻³⁹ g cm².

(IDEAL GAS)

Bond Distance: Mo-O = $[1.83 \pm 0.05] \text{ \AA}$ O-H = $[0.95 \pm 0.05] \text{ \AA}$
Bond Angle: O-Mo-O = $[109.5^\circ]$ H-O-Mo = $[104.5^\circ]$
O-Mo-OH plane perpendicular to O=MoO plane $\sigma = [2]$

Product of the Moments of Inertia: $I_A I_B I_C = [1.5399 \times 10^{-113}] \text{ g cm}^6$

Heat of Formation

The enhanced volatility of metallic molybdenum and molybdenum trioxide in the presence of water vapor at high temperatures has been investigated by several workers (1, 2, 3) using transpiration techniques. Glemser and Haeseler (1) and Butten (2) have shown that the major volatilization reaction of the oxide is:
 $\text{A. MoO}_3(\text{c}) + \text{H}_2\text{O}(\text{g}) \rightleftharpoons \text{MoO}_3(\text{OH})_2(\text{g})$
For the reaction of metallic molybdenum with water vapor, Balton and Jordan (3) reported the existence of $\text{MoO}_3(\text{OH})_2(\text{g})$ according to the equilibrium:
 $\text{B. Mo(c)} + 4\text{H}_2\text{O}(\text{g}) \rightleftharpoons \text{MoO}_3(\text{OH})_2(\text{g}) + 3\text{H}_2(\text{g})$

Second and third law analyses of these equilibrium data are summarized below.

Investigator	Reaction	Range, °K	No. of Points	ΔH_{298}° (kcal/mol)	Drift	$\Delta H_f^\circ(\text{MoO}_3(\text{OH})_2)$ kcal/mol
Glemser and Haeseler (1)	A	873-963	Equation	38.2	3rd Law	-4.2
Butten (2)	A	673-773	Equation	30.0	3rd Law	-204.0 ± 0.5
Balton and Jordan (3)	B	1473-1773	Equation	30.1	3rd Law	-203.7 ± 0.5
						-202.6 ± 0.3

The adopted value, $\Delta H_f^\circ(\text{MoO}_3(\text{OH})_2, \text{g}) = -203.4 \pm 1.0 \text{ kcal/mol}$, is an average of these three results.

Heat Capacity and Entropy

The assumed tetrahedral structure for $\text{MoO}_3(\text{OH})_2$ is from Jordan (4). The O-H bond length and H-O-Mo bond angle are assumed to be the same as for $\text{H}_2\text{O}(\text{g})$. The Mo-O bond length is from the compilation of Sutton (5) and assumed to be the same as for Ag_2MoO_4 . Individual moments of inertia are $I_A = 23.782 \times 10^{-39}$, $I_B = 25.415 \times 10^{-39}$, and $I_C = 25.478 \times 10^{-39} \text{ g cm}^2$.

The vibrational frequencies are estimated by comparison with those for $\text{H}_2\text{SO}_4(\text{g})$ (5, 7) and are adjusted to give $S^\circ(\text{MoO}_3(\text{OH})_2, \text{g}) = 137.4 \text{ gibbs/mol}$ at 1600°K. This entropy value is derived from a second law analysis of the equilibrium data for reaction B reported by Balton and Jordan (3).

Heat of Formation.

The heat of formation of amidogen at 298.15°K., ΔH_f⁰ (NH₂, g) = 39.8 kcal. mole⁻¹ was obtained from the pyrolysis of N₂H₄ by J. A. Kerr, R. C. Sekhar and A. P. Trotman-Dickenson, J. Chem. Soc. 3217 (1963). They have reinvestigated the rate constants of the thermal decomposition N₂H₄ → 2NH₂ at different temperatures using the same techniques as M. Szwarc, J. Chem. Phys. 17, 505 (1949), and revised the activation energy to 57.1 kcal. mole⁻¹ for the reaction at 874°K. (instead of 60 kcal. mole⁻¹ at 1000°K. reported by Szwarc). The activation energy was assumed to be the same as the dissociation energy of the N-N bond in hydrazine. Using all JANAF auxiliary data, one obtains D₀ (H₂N-NH₂) = 55.4 ± 3 kcal. mole⁻¹ and ΔH_f⁰ 298 (NH₂, g) = 40.1 ± 3 kcal. mole⁻¹.

F. M. Page, Trans. Faraday Soc. 57, 1254 (1961), has measured the electron affinity of NH₂ and has applied the results to calculate the dissociation energy, D₀ (H-NH₂) = 102 ± 3 kcal. mole⁻¹. This value leads to the heat of formation ΔH_f⁰ 298 (NH₂, g) = 40.4 ± 3 kcal. mole⁻¹ which is in good agreement with the value selected. E. R. Lippincott and M. O. Dayhoff, Spectrochim. Acta, 16, 807 (1960) calculated theoretically the dissociation energy D₀ (H₂N-NH₂) = 59 kcal. mole⁻¹ which gives ΔH_f⁰ 298 (NH₂, g) = 41.9 kcal. mole⁻¹.

Heat Capacity and Entropy.

The bond distance and angle were measured from the electronic absorption spectra of NH₂ by K. Dressler and D. A. Ransay, Phil. Trans. Roy. Soc. London Ser. A 252, 553 (1959). The three principal moments of inertia are I_A = 0.1189 X 10⁻⁵⁹ g. cm.², I_B = 0.2149 X 10⁻⁵⁹ g. cm.² and I_C = 0.3338 X 10⁻⁵⁹ g. cm.²

The selected vibrational frequencies were obtained from the infrared spectrum of NH₂ by matrix isolation by D. E. Milligan and M. E. Jacox, J. Chem. Phys. 43, 4487 (1965). K. N. Tanner and R. L. King, Nature 181, 963 (1958) have also determined the vibrational frequencies ω₁ = 3200 cm.⁻¹ and ω₂ = 3280 cm.⁻¹ by flash photolysis and calculated ω₂ = 1060 cm.⁻¹. The symmetric and the antisymmetric stretching frequencies are in good agreement. M. Taubol, Spectrochim. Acta 16, 505 (1960), has observed NH₂ bending frequencies, 1572 cm.⁻¹, 1819 cm.⁻¹ and 1623 cm.⁻¹, in HCONH₂(g), C₆H₅NH₂(g) and CH₃NH₂(g), respectively. In light of these observations and the adopted ω₂, Tanner and King's bending frequency seems to be in error.

Bond Distance: N-H = [1.014] Å N-N = [1.23] Å

Bond Angle: H-N-N = [100]°

Product of the Moments of Inertia: $I_A I_B I_C = [1.3988] \times 10^{-117} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The standard enthalpy of formation, ΔH_f^0 298 (N₂H₂) g = 50.9 kcal. mole⁻¹, was calculated from the appearance and ionization potentials of di-imide reported by S. N. Foner and R. L. Hudson, J. Chem. Phys. 29, 442 (1958), using the JANAF ΔH_f^0 (N₂H₂) g = 26.1 kcal. mole⁻¹ in calculation. For example:

 ΔH_f^0 
 $11.0 \pm 0.2 \text{ e.v.}$
 $9.85 \pm 0.1 \text{ e.v.}$
 $1.15 \pm 0.2 \text{ e.v.}$
 $(26.5 \pm 5 \text{ kcal. mole}^{-1})$

From the above heat of formation and that for NH(g) in the JANAF Tables 12-31-65, one can calculate a N-N bond energy of $109.4 \pm 5 \text{ kcal. mole}^{-1}$ at 0°K. This is in agreement with the N-N bond in molecules such as N₂P₂.

Heat Capacity and Entropy.

The bond distances and angle were obtained from a quantum-mechanical calculation by W. Wheland and P. S. K. Chen, J. Chem. Phys. 24, 67 (1956). The three principal moments of inertia are $I_A = [0.3116] \times 10^{-39}$, $I_B = [1.9686] \times 10^{-39}$ and $I_C = [2.2802] \times 10^{-39} \text{ g. cm.}^2$

Since there are 12 valency electrons in N₂H₂, A. D. Walsh, J. Chem. Soc. 2288 (1953), has predicted a bent ground state, existing in either a cis or a trans configuration for diimide. E. J. Blau and B. F. Hochheimer, J. Chem. Phys. 41, 1174 (1964), have measured the infrared spectrum of diimide which was frozen in a cold trap as one of the decomposition products of N₂H₄. The spectrum of the solid N₂H₂ at liquid nitrogen temperature agrees with the predicted non-linear planar structure, and the molecule N₂H₂ appears mainly in cis form. They have also assigned six fundamental vibrational frequencies for cis N₂H₂(s) which have been adopted here for gaseous cis N₂H₂. Blau and Hochheimer also observed two gas phase bands (1277 - 1314 and 3050 - 3190 cm.⁻¹). K. Rosengren and G. C. Pimentel, J. Chem. Phys. 43, 507 (1965), have observed these bands in matrix isolation studies. They assigned ω_1 or $\omega_4 = 3074 \text{ cm.}^{-1}$ and $\omega_3 = 1279 \text{ cm.}^{-1}$ which are in satisfactory agreement with the selected frequencies.

Products of the Moments of Inertia: I_AI_BI_C = [8.156754] X 10⁻¹¹⁴ g.³ cm.⁶

Heat of Formation.

See NaOH(g) table for details.

Heat Capacity and Entropy.

S. H. Bauer, R. H. Diner and R. P. Porter, J. Chem. Phys. 29, 921 (1958), have proposed a model for the dimeric alkali hydroxide (g) which consists of a square planar configuration for the alkali and oxygen atoms, with two hydrogen bridges between the oxygens (the hydrogen and oxygen atoms formed a rhombus perpendicular to the alkali-oxygen plane). R. C. Schoonmaker and R. P. Porter, J. Chem. Phys. 31, 830 (1959), have suggested a square planar model without hydrogen bonding with alkali-oxygen bond distances 0.2 Å larger than those assumed for the monomeric alkali hydroxides. J. Berkowitz, D. J. Meschi and W. A. Chupka, J. Chem. Phys. 33, 533 (1960), have also postulated a model for Li₂(OH)₂(g) which consists of a trans configuration with hydrogens above and below the plane of the rhombus, and the angle O-Li-O = 100°. The last one was adopted for the molecular configuration of Na₂(OH)₂, but the bond angle O-Na-O in Na₂(OH)₂(g) was assumed to be 110°. The bond distance O-H was estimated to be the same in H₂O(g). The three principal moments of inertia are I_A = [14.0631] X 10⁻³⁹, I_B = [18.1878] X 10⁻³⁹ and I_C = [31.8449] X 10⁻³⁹ g. cm.²The first six selected vibrational frequencies were taken to be equal to those for Na₂F₂(g) (see Na₂F₂(g) table), and the rest were O-H stretching and bending frequencies which have been suggested by Berkowitz et al., loc. cit.

Product of Moments of Inertia I_AI_BI_C = 5.7558 × 10⁻¹²⁰ g.³ cm.⁶

Heat of Formation

Taken from National Bureau of Standards Circular 500, "Selected Values of Chemical Thermodynamic Properties," 1952.

Heat Capacity and Entropy

A. S. Friedman and L. Haar, J. Chem. Phys. **22**, 2051 (1954), using the infra-red spectra analysis of W. S. Benedict, K. H. Claassen and J. H. Shaw, J. Research Natl. Bur. Standards **49**, 91 (1952), have calculated the thermodynamic functions for water including the anharmonic corrections. Friedman and Haar in comparing their calculation to that of a direct summation by Glatt, Adams, and Johnston, Ohio State University Res. Foundation Tech. Report No. 316-8 (1953), found that the difference between the two calculations was less than the uncertainty in the direct summation.

C_p values from 100° to 5000°K. are from Friedman and Haar. C_p from 5000° to 6000°K. was extrapolated linearly. Using the tabulated functions of Friedman and Haar C_p, S, and H_{298.15}°K. was calculated by the method of Lagrangian curvilinear interpolation, W. J. Taylor, J. Research Natl. Bur. Standards **35**, 151 (1945).

The bond length and angle were obtained from a compilation by L. E. Sutton, "Tables of Interatomic Distances and Configurations in Molecules and Ions," The Chem. Soc., Burlington House, London W1, 1958.

Heat of Formation.

The heat of combustion (ΔH_c°) of rhombic sulfur (c) to H₂SO₄(aq), i.e., S(c, rhombic) + 3/2 O₂(g) + H₂O(l) = H₂SO₄(aq), has been determined by many investigators. Based on the reported ΔH_c° data, values of $\Delta H_f^{298}(\text{H}_2\text{SO}_4, \text{l})$ are derived using heats of solution and dilution for H₂SO₄(l), taken from D. D. Wegman, W. H. Evans, I. Hallow, V. B. Parker, S. M. Bailey and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Technical Note 270-1, Natl. Bur. Std., 1965. The results obtained are presented in the table below. The value of $\Delta H_f^{298}(\text{H}_2\text{SO}_4, \text{l})$ is adopted as -194.548 ± 0.10 kcal/mol, which is the same as that given by Technical Note 270-1, loc. cit.

Investigator	Product	ΔH_c° , kcal/mol	ΔH_f^{298} , kcal/mol
1. McCullough et al. (1963)	H ₂ SO ₄ (70H ₂ O)	-143.58 ± 0.09	-194.400

- D. W. Scott, J. P. McCullough, W. N. Hubbard, J. F. Measlerly, I. A. Hosenlopp, F. R. Frow and O. Vaddington, *J. Am. Chem. Soc.* **78**, 5463 (1956).
- J. D. Good, J. L. Lachina and J. P. McCullough, *J. Am. Chem. Soc.* **82**, 5589 (1960).
- M. Mansson and S. Sumner, *Acta Chem. Scand.* **17**, 723 (1963).

Heat Capacity and Entropy.

The heat capacities, 283.46 to 300°K, were measured by W. P. Glaque, E. W. Hornung, J. E. Kunzler, and T. R. Rubin, *J. Am. Chem. Soc.* **82**, 62 (1960). The Cp values above 300°K are obtained from graphical extrapolation. The value of S°₂₉₈ was reported by Glaque, Hornung, Kunzler and Rubin, loc. cit., based on low temperature heat capacity measurements of H₂SO₄(c).

Melting Data.

T_m and ΔH_m° are taken from T. R. Rubin and W. P. Glaque, *J. Am. Chem. Soc.* **74**, 800 (1952). The value, T_m=283.53°K, has been reported by C. M. Gable, H. P. Betz and S. H. Maron, *J. Am. Chem. Soc.* **72**, 1445 (1950), as well as J. E. Kunzler and W. P. Glaque, *J. Am. Chem. Soc.* **74**, 797 (1952). The heat of melting (ΔH_m°) has also been determined by the following investigators:

ΔH_m° , kcal/mol	Source
2.35	Pickering, <i>Proc. Roy. Soc. (London)</i> 49 , 11 (1891).
2.25	Hantzsch, <i>Z. Physik. Chem.</i> 61 , 262 (1907).
2.24	Krietsch, quoted by Hantzsch, loc. cit.
2.55	Brönsted, <i>Z. Physik. Chem.</i> 58 , 693 (1910).
2.56	Rubin and Glaque, <i>J. Am. Chem. Soc.</i> 74 , 800 (1952).

Vaporization Data.

T_b is the temperature at which the Gibbs energy change (ΔG_r°) for the reaction H₂SO₄(l) = H₂SO₄(g) approaches zero. The difference between ΔH_f° for H₂SO₄(g) and H₂SO₄(l) at T_b is ΔH_v° .

According to G. P. Lucinaki, *Zh. Fiz. Khim.* **30**, 1207 (1956), the total vapor pressure over H₂SO₄(l) reaches one atmosphere at 553°K with a vapor composition of 76.6 mole percent SO₃, 22.6% H₂SO₄, and 0.8% H₂O. This composition implies that the real liquid phase enhances the vapor decomposition by reducing the partial pressure of water vapor.

Heat of Formation

The vapor phase equilibria of the H_2SO_4 , H_2O and SO_3 systems have been studied by (1) B. Bodenstein and M. Katayama, Z. Elektrochem. 15, 244 (1909), Z. Physik. Chem. 69, 26 (1909); (2) G. P. Luchinskii, Zh. Fiz. Khim. 30, 1207 (1956), and (3) A. V. Suvorov, R. B. Dobrovin and S. M. Gashler, Russ. J. Inorg. Chem. (English Transl.) 10, 710 (1965). The data of Bodenstein and Katayama and of Suvorov et al. were obtained from PVT studies, while those of Luchinskii were based on vapor pressure measurements. A translation of Luchinskii's paper is not yet available, so it is not known whether he obtained the vapor composition experimentally or by calculation. Using the reported equilibrium values for the reaction $H_2SO_4(g) = H_2O(g) + SO_3(g)$, we evaluate the corresponding enthalpy changes by both the second and third law methods. The results are presented in the table below. The value of ΔH_{298}° for $H_2SO_4(g)$ is adopted as -177 ± 2 kcal/mol.

Investigator	Temp., °K	No. of Points	ΔH_{298}° , kcal/mol	Drift, kcal/mol
1. Bodenstein & Katayama (1909)	596-2-756.2	53	-22.95 \pm 0.66	-24.55 -2.3 \pm 1.0 -176.94
2. Luchinskii (1956)	333-2-473.2	8	-24.02 \pm 0.22	-24.43 -1.2 \pm 0.5 -176.82
3. Suvorov (1965)	583-0-713.0	40	-27.14 \pm 0.45	-24.90 +3.3 \pm 0.6 -177.29

*Calculation based on the third law ΔH_{298}° value.

Heat Capacity and Entropy

The molecular structure and bond angles (O-S-O, HO-S-OH) are estimated by comparison with those for $SO_2(g)$ reported by D. R. Lide, D. E. Mann and R. M. Fristrom, J. Chem. Phys. 26, 754 (1957). The S-O and S-OH bond distances are assumed to be the same as those in $H_2SO_4(c)$, determined by R. Pascard, Compt. Rend. 240, 2162 (1955). The OH distance and S-O-H angle are taken from those for $H_2O(g)$. Electric deflection studies by A. Böhler, J. L. Stauffer and M. Knepper, J. Chem. Phys. 45, 605 (1967), indicate that $H_2SO_4(g)$ is polar, which is consistent with the assumed C_{2v} structure.

The infrared absorption spectrum in the range 4000 to 400 cm⁻¹ of normal and deuterated $H_2SO_4(g)$ above $H_2SO_4(l)$ was observed by S. M. Chackalal and P. E. Stafford, J. Am. Chem. Soc. 89, 723 (1967). The authors assigned nine vibrational frequencies, which are adopted here. The three principal moments of inertia are: $I_A = 1.570 \times 10^{-38}$, $I_B = 1.586 \times 10^{-38}$, and $I_C = 1.702 \times 10^{-38}$ g cm².

Four of the six missing frequencies are obtained from P. A. Giguère and R. Savoie, J. Am. Chem. Soc. 85, 287 (1963), which were estimated by comparison with infrared frequencies for the crystal and Raman values for the liquid. The remaining two frequencies, $\nu_7 = 450$ and $\nu_{14} = 450$ cm⁻¹, are assigned arbitrarily so that the second and third law values for $\Delta H_{298.15}^\circ$ derived from equilibrium data are in reasonable agreement.

Td = [393]°K

Heat of Formation

V. I. Spitsyn and N. M. Patsukova¹ have measured calorimetrically the heats of reaction (1) and (2) at 298°K as -13.80 ± 0.01 and -13.05 ± 0.02 kcal/mol, respectively. The reactions are given as follows:

Combination of reactions (1) and (2) gives ΔH_f²⁹⁸ = -0.75 ± 0.04 kcal/mol for WO₃(c) + H₂O(l) → H₂WO₄(c), which leads to ΔH_f²⁹⁸(H₂WO₄, c) = -270.5 ± 0.4 kcal/mol.

To obtain WO₃(c) in a form soluble in the calorimetric solution, Spitsyn and Patsukova dehydrated H₂WO₄(c) at the relatively low temperature of 250°C. The resulting WO₃(c) was a very fine lemon-yellow powder which may have excess surface free energy compared with the JANAF standard state. The latter is WO₃ formed at high temperature in a calorimetric bomb. The actual heat of formation of tungstic acid should be less negative if this effect is significant.

The previously accepted value^{2,3,4} -280.2 ± 0.4 kcal/mol, was based on the pressure-temperature-composition studies of G. P. Rutting and B. Kurte⁵ for the WO₃-H₂O system. We suspect that the data do not correspond to equilibrium (see entropy section) for the reaction H₂WO₄(c) → WO₃(c) + H₂O(g).

Heat Capacity and Entropy

C_p300 = 27.0 gibbs/mol is estimated using Kopp's rule. Since the decomposition temperature of H₂WO₄(c) is approximately 400°K, which is relatively low for hydrogen and oxygen to reach their maximum Cp contribution, we estimate Cp400 = 31.0 gibbs/mol for H₂WO₄(c).

The entropy, S₂₉₈^a = 34.6 eu, is estimated so that the decomposition pressure of water is one atmosphere at 120°C. This value is quite uncertain as suggested by comparison with the following estimates. A lower limit may be obtained from S_{283.5}^a = 26.8 eu for H₂SO₄(c). Summation of the entropies for WO₃(c) and H₂O(g) [10.7 eu] yields 28.8 eu, an estimate which is somewhat larger than the lower limit. An upper limit may be obtained by assuming that the pressure of about 14 mm at 190°C corresponds to equilibrium for the reaction H₂WO₄(c) = WO₃(c) + H₂O(g). This pressure, based on the plateau in the temperature-composition data of Rutting and Kurte⁵, yields S₂₉₈^a = 46.5 eu when combined with the adopted ΔH_f²⁹⁸ and JANAF auxiliary data. Since the estimate appears to be unreasonably large, we suggest that this region of the curve may correspond to the reaction WO₃·0.5 H₂O(c) = WO₃(c) + 0.5 H₂O(g). In contrast, the observed pressures⁵ for samples having mole ratios (H₂O/WO₃) of 1.2 - 1.35 leads to S₂₉₈^a = 34 eu, if the reaction is WO₃·H₂O(c) = WO₃(c) + H₂O(g).

Temperature of Decomposition

Td is calculated as the temperature at which the Gibbs energy change of the reaction H₂WO₄(c) → WO₃(c) + H₂O(g) approaches zero.

Spitsyn and Patsukova¹ observed that some dehydration of stoichiometric H₂WO₄(c) occurs at temperatures as low as 90°C. Thermal studies^{6,7} on tungstic acid containing some excess water indicated the start of dehydration somewhere in the region of 60 - 120°C. These temperatures yield a lower limit for Td on the presumption that the experiments correspond to a partial pressure of water of less than one atmosphere.

Heat of Formation

The adopted heat of formation, ΔH²⁹⁸ = -216.5 ± 1.0 kcal/mol, is derived from equilibrium data^{1,2,3,4,5} obtained by the transpiration method. The data are in reasonable agreement and they are summarized below. Beaton and McCarron¹ have concluded that W₃H₂O is the species responsible for the increased volatilization of W(c) and W₃(c) in the presence of water vapor. Based on their data for W(c) and the earlier data for W₃(c), Beaton and McCarron¹ ruled out the possibility of significant amounts of (W₃)₂·H₂O and W₃·2 H₂O.

Heat Capacity and Entropy

The vibrational frequencies are estimated by comparison with those for H₂SO₄(g) reported by P. A. Diguere and R. Savoie, J. Am. Chem. Soc. **85**, 287 (1963), and S. M. Chakraborty and P. E. Stafford, J. Am. Chem. Soc. **88**, 723 (1966). These frequencies are also adjusted so that S^{298.15}(H₂WO₄,g) is 136.7 eu as reported by Beaton and McCarron, loc. cit. This entropy was derived from second law analysis of the equilibrium constants for reaction A.

The configuration of W₃ group is assumed to be tetrahedral. The bond angle W-O-H is estimated to be the same as the angle of H₂O(g). The bond distances are assumed to be the same as those in W₃(g) and H₂O(g). The three principal moments of inertia are I_A = 2.328 x 10⁻³⁶, I_B = 2.487 x 10⁻³⁶ and I_C = 2.493 x 10⁻³⁶ g cm².

PHOSPHORUS HYDRIDE (PH₂)

(IDEAL GAS)

Point Group [C_{2v}]
ΔH_f⁰ = [30.6 ± 23] kcal. mole⁻¹
S_{298.15} = [50.8] cal. deg⁻¹ mole⁻¹
ΔH_f⁰ 298.15 = [30.1 ± 23] kcal. mole⁻¹
Ground State Multiplicity = [2]

Vibrational Frequencies and Degeneracies

ω, cm ⁻¹	[2327] (1)	[1020] (1)	[2322] (1)
---------------------	------------	------------	------------

Bond Distances: P-H = [1.419] Å

Bond Angle: H-P-H = [93.7]°

Product of Moments of Inertia: I_AI_BI_C = [6.95 X 10⁻¹¹³] g.³ cm.⁶

σ = 2

Heat of Formation.

ΔH_f⁰ 298.15 was estimated by V. N. Distefano, R. L. Potter, and S. N. Fox, "The Thermodynamic Functions of Some Combustion Products Containing Phosphorus-I.", American Cyanamid Company. The ΔH_f⁰ 298.15 was estimated by taking 83% of the dissociation energy of PH₂ and using it as the dissociation energy of PH₂. D. Wiles and C. Minkler, J. Phys. Chem. 61, 302 (1957) have estimated the ΔH_f⁰ 298.15 for PH₂(g) to be 30 kcal. mole⁻¹.

Heat Capacity and Entropy.

The vibrational spectra of PH₂ from the flash photolysis of PH₃ has been reported by D. A. Ramsay, Nature 179, 375 (1956) and in N. Y. Acad. Sci. 61, 485, (1957). Similarities between the spectra of NH₂ and PH₂ were found. For NH₂ and NH₃ bond angles and bond distances were reported to be about the same. By analogy then the bond angles and bond distances of PH₂ and PH₃ should be nearly the same. The moments of inertia for PH₂ were therefore calculated from the molecular constants for PH₃. The principal moments were found to be I_A = 3.587 X 10⁻⁴⁰ g. cm.², I_B = 2.959 X 10⁻⁴⁰ g. cm.², and I_C = 6.546 g. cm.² X 10⁻⁴⁰.

Distefano and Potter (loc. cit.) have assumed the ground state degeneracy to be 2, because of the unpaired electron. The vibrational frequencies reported by Distefano and Potter (loc. cit.) have been used. They used a simple force field and the force constants of PH₃ to obtain the vibrational frequencies.

Heat of Formation.

The heat of formation of hydrogen sulfide has been calorimetrically measured by H. Zeumer and W. A. Roth, Z. Elektrochem. 40, 777 (1934), and A. P. Kapustinikii and R. T. Kankovskii, Zhur. Fiz. Khim. 32, 2810 (1958), as ΔH_f^o 293 = -4.80 ± 0.15 kcal. mole⁻¹ and ΔH_f^o 298 = -4.94 ± 0.08 kcal. mole⁻¹, respectively. A weighted average of these two values was taken for the standard enthalpy of formation of hydrogen sulfide.

Heat Capacity and Entropy.

The bond distance, angle and vibrational frequencies were obtained from H. C. Allen, Jr. and E. K. Plyler, J. Chem. Phys. 25, 1132 (1956).

J. S. Gordon, private communication, Feb. 7, 1961, has calculated C_p from 298 to 6000°K. by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes second order corrections for vibrational anharmonicity, vibration-rotation interaction, and centrifugal stretching into account. The correction constants were obtained from Allen and Plyler, loc. cit. Below 298°K. the rigid-rotator harmonic oscillator method was used to calculate the functions, but at 298°K. and above Gordon's thermodynamic functions were adopted in this tabulation.

$$\Delta H_f^0 = [-32.5 \pm 2.0] \text{ kcal. mole}^{-1}$$
$$\Delta H_f^{298.15} = [-34.5 \pm 2.0] \text{ kcal. mole}^{-1}$$
$$S_{298.15}^0 = 7.101 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

Heat of Formation.

The heat of combustion of TiH_{1.73}(c), the stable species of titanium hydride, was reported to be -247.8 kcal. by A. Sieverts and A. Gotta, Z. anorg. allgem. Chem. 199, 384 (1931). From this data the value of ΔH_f^{298.15} for TiH_{1.73}(c) was calculated to be -29.40 kcal. mole⁻¹. The heat of dissociation of titanium hydride having compositions between the rough limits TiH_{1.75}-TiH_{1.93} was given as 19.15 kcal. per mole of H₂ dissociated by T. R. P. Gibb, Jr., J. McSharry, and R. W. Bragdon, J. Am. Chem. Soc. 73, 1751 (1951). Assuming this value is applicable to compositions between the limits TiH_{1.73}-TiH₂, the difference in the heat of formation of titanium hydride between TiH_{1.73} and TiH₂ was estimated to be -5.17 kcal. mole⁻¹. Thus the value of ΔH_f^{298.15} for TiH₂(c) was calculated.

Heat Capacity and Entropy.

The low temperature C_p for TiH_{1.97}(c), 24-363°K., were measured by B. Stalinski and Z. Bieganski, Bull. Acad. Polon. Sci., Ser. Sci. Chim., 9, No. 5, 243 (1960). This data were adopted for TiH₂(c) due to lack of the measured C_p values. A small but well marked λ-type anomaly with a maximal value of C_p at 288.5°K. in the C_p vs. T curve was observed. S_{298.15} was reported by B. Stalinski and Z. Bieganski, loc. cit., based on S₂₅(extrap.) = 0.065 cal. deg.⁻¹ mole⁻¹.

Heat of Formation

A weighted average based on analysis using JANAF functions was selected. Haber, Tammaru and Oeholm, Z. Elektrochem. 21, 206 (1915) obtained $\Delta H_{298}^0 = 11.10$ for NH₃ from 0.5 H₂ + 1.5 H₂ by flow calorimetry. Estimated uncertainty is 1% and the formation value was corrected by 0.025 kcal. for non-ideality of NH₃. Becker and Roth, ibid. 20, 836 (1934) measured ΔH_f^0 for NH₃ from the heat of formation of H₂O and (NH₄)₂CO₃, and the necessary ΔH_{298}^0 leading to $\Delta H_{298}^0 = 182.9 \pm 0.24$ for 3H₂O(l) + N₂(g) → 2NH₃(g) + 2H₂O(l). Equilibrium data from Larson and Dodge, J. Am. Chem. Soc. 45, 2918 (1923) and Haber, Tammaru and Ponnaz, Z. Elektrochem. 21, 89 (1915) were analyzed as tabulated by Stephenson and McMahon, J. Am. Chem. Soc. 61, 437 (1939) from the non-ideality corrections of Gillespie and Beattie, Phys. Rev. 56, 743 (1930). Data (1000-3000 atm) from Winchester and Dodge, A.I.Ch.E. Journal 2, 128 (1915) were assumed ideal. High-temperature calorimetry of the direct decomposition includes Haber and Tammaru, Z. Elektrochem. 21, 191 (1915) and Wittig and Schmatz, ibid. 63, 470 (1959).

*Third law values for equilibrium data are followed by second law values in parentheses.

Heat Capacity and Entropy

The functions are an approximation of the non-rigid rotator anharmonic oscillator based on calculations of Harrison and Kobe, Chem. Eng. Progr. 49, No. 7, 349 (1953) and Yungman, Gurvich and Ritscheva, Trudy Gosudarst. Inst. Priklad. Khim. 49, 20 (1962). In these calculations anharmonicity of ν_2 associated with inversion doubling was treated by summation over the energy levels. Both calculations include rotational distortion corrections while Yungman, et al., also allow for anharmonicity and vibration-rotation interaction of the other fundamentals. JANAF functions agree with the results to within 0.02 e.u. in the range 298-1500°K.

Two sets of rigid rotator harmonic oscillator functions were also tested for consistency with the ammonia data (see below). These were obtained from molecular dimensions and either calculated zero order frequencies (ω_e) or observed wave numbers (ω_e) obtained by Benedict and Plyler, Can. J. Phys. 35, 1235 (1957) from high resolution infrared studies. Herzberg, "Infrared and Raman Spectra", pp. 503-4, 1945 states that ω_e should be used and the RRHO⁰ functions give better, but not perfect, agreement with the observed C_p^0 for NH₃. Principal moments of inertia are $I_A = 4.414 \times 10^{-40}$ and $I_B = I_C = 2.809 \times 10^{-40} \text{ cm.}^2$. Electron diffraction studies by Bastiansen and Besley, Acta Chem. Scand. 18, 2077 (1964) give slightly different constants (bond distance 1.015 Å and angle = 109.1°).

T, °K	Heat Capacity, C _p		Entropy, S°

800.	12.070-2(f)	12.225	800.	55.99

(a) M. S. Osborne, H. P. Stinson, T. S. Slichter, Jr., and G. S. Crago, NBS Sci. Papers 20, 85 (1924-6) measured C_p of gaseous NH₃ (258 to 423°K and 0.5 to 20 atm) within an estimated maximum error of 0.3% (about 0.03 cal. deg.⁻¹ mole⁻¹) and obtained C_p by use of a suitable equation of state.

(b) R. Overstreet and W. P. Giauque, J. Am. Chem. Soc. 59, 254 (1937) determined the entropy of the real gas at the normal boiling point as $S_{239.72}^0 = 44.06 \pm 0.10 \text{ cal. deg}^{-1} \text{ mole}^{-1}$.

(c) (S-S)_{239.72} = 0.17 cal. deg.⁻¹ mole⁻¹ from the virial coefficient equation derived by Hirschfelder, McCure and Weeks, J. Chem. Phys. 10, 201 (1942) from the PVT data of Meyers and Jessup, Refrig. Eng. 11, 345 (1925).

(d) Combination of ΔH_f^0 800 = -12.85 kcal. mole⁻¹ from the calorimetric measurement of F. E. Wittig and W. Schmatz, Z. Elektrochem. 63, 470 (1959) with ΔH_f^0 = 9.315 kcal. mole⁻¹ from equilibrium data (f).

(e) Second law analysis of the equilibrium data (f).

(f) K_p values based on the equilibrium data of Haber, Tammaru and Ponnaz and of Larson and Dodge were analyzed by regression analysis to give $\Delta H_{800}^0 = 9.315 \pm 0.004$, $\Delta H_{800}^0 = -12.666 \pm 0.017$ and ΔC_p 800 = -2.51 ± 0.20.

Product of the Moments of Inertia: I_AI_BI_C = [2.59] X 10⁻¹¹⁹ g³ cm⁶

σ = 3

Heat of Formation

The proton affinity of water has been measured by the ion impact method as -169 kcal/mol by V. L. Tal'rose and E. L. Frankvitch, Doklady Akad. Nauk SSSR 111, 376 (1956), J. Am. Chem. Soc. 80, 2344 (1958). The selected heat of formation of hydronium ion, ΔH_f^o(H₃O⁺, g) = 139.1 kcal/mol, was derived from the ΔH_f^o = -169 kcal/mol for H₂O(g) + H⁺(g) → H₃O⁺(g), using the JANAF ΔH_f^o(H₂O, g) = -57.1 and ΔH_f^o(H⁺, g) = 385.2 kcal/mol.

The values of 195 and 207 kcal/mol for the heat of formation of H₃O⁺(g) have also been reported by P. M. Field and J. L. Franklin, "Electron Impact Phenomena," Academic Press, New York, 1957, and R. R. Berner and P. A. Long, J. Phys. Chem. 65, 1565 (1961), respectively. These two values were based on the electron impact studies which may involve unaccounted excitations and excess energy in the fragments. Other literature values have been reviewed by D. M. Bishop, J. Chem. Phys. 43, 4453 (1965).

J. A. Green and T. M. Sugden, Ninth Symposium (International) on Combustion, Academic Press, New York, 1963, based on the studies of the positive ions in flames by mass spectrometry, prefer the value derived from the proton affinity of water obtained by Tal'rose and Frankvitch, rather than the electron impact data. From the approximate equilibrium constant calculations for the reaction HCO⁺(g) + H₂O(g) ⇌ H₃O⁺(g) + CO(g), D. G. Clifton, AD44078, G. M. Defense Research Laboratory, General Motors Corp., Santa Barbara, Calif., July 1964, has also found that the heat of formation of H₃O⁺(g) derived from the proton affinity of water, not from the electron impact data, leads to agreement with the experimental data given by Green and Sugden.

Heat Capacity and Entropy

Since the molecule H₃O⁺(g) has the same number of valence electrons as NH₃(g), a pyramidal molecular configuration (C_{3v}) is assumed for H₃O⁺(g) in the tabulation. D. G. Clifton, J. Chem. Phys. 41, 3656 (1964), has obtained a bond distance O-H of 0.95 Å from an application of covalent bond radii and the effect of electric charge, and a bond angle H-O-H of 109° by extrapolating a plot of bond length versus bond angle for NH₃(g) and PH₃(g) to 0.95 Å. Both values are adopted in the tabulation. The three principal moments of inertia are I_A = 0.4004 X 10⁻³⁹, I_B = I_C = 0.2445 X 10⁻³⁹ g cm². D. M. Bishop, loc. cit., has calculated theoretically the bond distance H-O of 0.95 Å and the bond angle H-O-H of 114° 26' with a planar D_{3h} molecular configuration. The vibrational frequencies were calculated by the valence force method from the estimated stretching and bending force constants of Clifton.

(CRYSTAL)
MOL. WT. = 97.999

$$\Delta H^\circ_f 0 = -297.5 \pm 0.3 \text{ kcal. mole}^{-1}$$

$$\Delta H^\circ_m = 3.100 \text{ kcal. mole}^{-1}$$

$$S^\circ_{298.15} = 26.42 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 315.51^\circ \text{K}$$

Heat of Formation.

The heat of formation was determined by W. S. Holmes (private communication July 5, 1962, Albright and Wilson (WPA) Ltd., Oldbury, Birmingham, Great Britain (in press by Paraday Society)). W. S. Holmes measured the enthalpy of combustion of white phosphorus (α form) in oxygen in a bomb calorimeter. The product, P_4O_{10} (hexagonal), was hydrolyzed in 10N perchloric acid to give H_3PO_4 . Measurement of the enthalpy of solution of $H_3PO_4(c)$ then enabled the ΔH°_f 298.15 to be calculated according to the following cycle:

* All ΔH°_f 's were measured.

E. P. Egan, Jr. and B. B. Luff, J. Phys. Chem., 65, 523 (1961), from partial molal heat contents of H_3PO_4 solutions found that a smooth extrapolation to 100% H_3PO_4 would give them a ΔH°_f 298.15 for $H_3PO_4(c)$ which was 755 cal. mole⁻¹ greater than the ΔH°_f 298.15 reported in the National Bureau of Standards Circular 500. The Circular 500 (loc. cit.) heat of formation refers to the work of Thomson, "Thermochemische Untersuchungen," Vol. 2, Barth, Leipzig (1882-1886). The heats of formation summarized:

ΔH°_f 298.15	Source
-305.7 \pm 0.3 kcal. mole ⁻¹	W. S. Holmes (loc. cit.)
-306.2 kcal. mole ⁻¹	Circular 500 (loc. cit.)
-305.4 kcal. mole ⁻¹	Egan and Luff (loc. cit.)
The selected ΔH°_f 298.15, -305.7 \pm 0.3 kcal. mole ⁻¹ , was corrected by +4.17 kcal. mole ⁻¹ , which is the ΔH°_f 298.15 of white (α) phosphorus.	

Heat Capacity and Entropy.

Third law entropy was calculated from the low temperature heat capacities measured by E. P. Egan, Jr. and Z. T. Wakefield, J. Phys. Chem. 61, 1500 (1957).

Melting.

The heat of fusion, ΔH°_m , was reported by E. P. Egan, Jr. and B. B. Luff, J. Phys. Chem. 65, 523 (1961) from ΔH°_m data measured by E. P. Egan, Jr. and Z. T. Wakefield, J. Phys. Chem. 61, 1500 (1957). The melting point $T_m = 315.51^\circ \text{K}$ was taken from the work of W. H. Rose and R. N. Jones, J. Am. Chem. Soc. 47, 2185 (1925).

Heat of Formation

The heat of formation was derived by S. R. Gunn and L. G. Green, J. Phys. Chem., **65**, 779 (1961). In order to obtain the ΔH_f^o 298.15 they measured the heat of explosive decomposition of phosphine gas. There is a good deal of uncertainty about the heat of formation of PH₃(g), for instance:

ΔH_f^o 298.15
+3.6 kcal mole⁻¹

+6.3 kcal mole⁻¹

-2.34 kcal mole⁻¹

+1.6 kcal mole⁻¹

Source
The heat of reaction between gaseous PH₃ and saturated bromine water. M. J. Ogier, Ann. Chim. Phys., **20**, 5 (1880).

The heat of combustion of PH₃(g) in O₂(g) to form H₃PO₄. M. P. Lemoult, Compt. Rend., **115**, 374 (1907).

Equilibrium data of W. N. Ipatiev, and A. W. Frost, Ber. dtsh. chem. Ges., **63B**, 1104 (1930). Their data showed a wide variation in ΔH, as much as 11 kcal mole⁻¹.

National Bureau of Standards, Report No. 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," 1 January 1962 (page 80-91).

The heats of formation have been reviewed by T. L. Cottrell, "The Strength of Chemical Bonds," Butterworth's Scientific Publications, London, (1958); and by F. R. Bichowsky and F. D. Rossini, "The Thermochemistry of The Chemical Substances," Reinhold Publishing Corp., New York (1936).

The heat of formation selected was, +1.3 ± 0.4 kcal mole⁻¹, as reported by Gunn and Green (loc. cit.). The selected heat of formation was based on white (g) phosphorus and thus required an adjustment for the red (V) phosphorus reference state.

Heat Capacity and Entropy

The Fundamental wave number and degeneracy assignments are from the infrared spectral data by V. N. McConaghie and H. H. Nielsen, J. Chem. Phys., **21**, 1836, (1953). The molecular constants are those obtained from infrared data by H. H. Nielsen, J. Chem. Phys., **20**, 759 (1952). Nielsen (loc. cit.) has reported the molecular constants after calculating the Coriolis coupling effect between the wave numbers 2 and 4, or (892 cm⁻¹) and (1122.4 cm⁻¹).

HYDRAZINE (N₂H₄)

(LIQUID)

MOL. WT. = 32.04528

S_{298.15} = 29.05 ± 0.1 cal. deg.⁻¹ mole⁻¹
 T_m = 274.69°K.
 T_b = 386.9°K.

ΔH_f^o 298.15 = 12.10 ± 0.1 kcal. mole⁻¹
 ΔH_m^o = 3.025 kcal. mole⁻¹
 ΔH_v^o = 9.70 kcal. mole⁻¹

Heat of Formation.

A. M. Hughes, R. J. Corruccini and E. C. Gilbert, J. Am. Chem. Soc. **61**, 2659 (1939), measured the heats of combustion of hydrazine and hydrazine monohydrate. The data, adjusted as suggested by L. G. Cole and E. C. Gilbert, J. Am. Chem. Soc. **73**, 5423 (1951), are summarized below. Heats of solution determined by V. C. Bushnell, A. M. Hughes and E. C. Gilbert, J. Am. Chem. Soc. **59**, 2142 (1937) interrelate N₂H₄(l) and N₂H₄·H₂O(l). An intermediate value was selected from the resulting heats of formation.

Source	Reaction	ΔH _f ^o 298	ΔH _f ^o 298
Hughes	N ₂ H ₄ (l) + O ₂ (g) → N ₂ (g) + 2H ₂ O(l)	-148.68 ± 0.06	12.05
Hughes	N ₂ H ₄ ·H ₂ O(l) + O ₂ (g) → N ₂ (g) + 3H ₂ O(l)	-147.00 ± 0.06	—
Bushnell	N ₂ H ₄ (l) + H ₂ O(l) → N ₂ H ₄ ·H ₂ O(l)	-1.80	12.17*

*From combination of second and third reactions.

Heat Capacity and Entropy.

Heat capacities (12-340°K) of hydrazine crystal and liquid were determined by D. W. Scott, G. D. Oliver, M. E. Gross, W. N. Hubbard and H. M. Huffman, J. Am. Chem. Soc. **71**, 2293 (1949). Values beyond the experimental range for the liquid were extrapolated linearly. The entropy was obtained from the heat of melting and the smoothed heat capacities of the crystal using S₁₂^o = 0.023 cal. deg.⁻¹ mole⁻¹.

Melting Data.

Taken from Scott et al., loc. cit.

Vaporization Data.

The normal boiling point and heat of vaporization are those calculated for the ideal gas from these tables. The boiling point found for the real gas (387.3°K) by W. Hieber and A. Woerner, Z. Elektrochem. **40**, 252 (1934) is in good agreement. The selected heat of vaporization, ΔH_v^o 298 = 10.69 kcal. mole⁻¹, is based on the vapor pressure data of Scott et al., loc. cit., series III. Vapor pressure measurements of Hieber and Woerner, loc. cit., and E. T. Chang and N. A. Gokcen, AD-458286, Defense Documentation Center, January, 1964, are in satisfactory agreement as shown below.

Source	Temp. Range °K.	ΔH _v ^o 298 (kcal. mole ⁻¹) 2nd Law	ΔH _v ^o 298 (kcal. mole ⁻¹) 3rd Law	3rd Law Drift e.u.
Scott, et al. (1949)	275-345	10.683 ± 0.003	10.696	0.05 ± 0.01
Chang, Gokcen (1964)	276-325	10.40 ± 0.03	10.68	0.91 ± 0.09
Hieber, Woerner (1934)	293-357	10.82 ± 0.03	10.71	-0.33 ± 0.07

The second law-third law consistency of Scott et al. reflects the use of these data in selection of the gas phase functions (see H₂N₂ gas).

 Torsional angle between two NH₂ groups ≥ 90° from eclipsed position.
 Product of the Moments of Inertia: I_AI_BI_C = 7.307 X 10⁻¹¹⁷ g.³ cm.³

Heat of Formation.

This was obtained from the heat of formation of the liquid and the selected heat of vaporization, $\Delta H_{298}^{\circ} = 10.69$ kcal. mole⁻¹, derived from the vapor pressure data (Series III) of D. W. Scott, G. D. Oliver, M. E. Gross, W. N. Hubbard and H. M. Huffman, J. Am. Chem. Soc. **71**, 2293 (1949). Other vapor pressure data from W. Kieber and A. Woerner, Z. Elektrochem. **40**, 252 (1934) and E. T. Chang and N. A. Ockers, AD-458288, Defense Documentation Center, January, 1964, are in satisfactory agreement (see N₂H₄ liquid table).

Heat Capacity and Entropy.

Functions were calculated from the constants given above using the rigid rotator harmonic oscillator method. The entropy was increased by R ln 2 because two rotameric forms are implied by use of the torsional frequency. Small but arbitrary adjustments were made in the assignment of the bending mode frequencies in order to reproduce the vapor pressure data of Scott et al., loc. cit., as closely as possible. Calculated values of $S_{298}^{\circ} = 57.03$ and $S_{340}^{\circ} = 58.70$ cal. deg.⁻¹ mole⁻¹ may be compared with 56.99 and 59.69, respectively, derived from the data of Scott et al.. Internal rotation calculations would require a complex potential function in order to fit the data. The barrier to inversion (990 cm.⁻¹ ~ 2.8 kcal.) is slightly less than the barrier to internal rotation at the trans position (1110 cm.⁻¹ ~ 3.2 kcal.) according to analyses of the microwave data by T. Kasuya, Sci. Papers, Inst. Phys. Chem. Res. (Tokyo) **55**, No. 1, 1-39 (1962) and T. Kasuya and T. Kojima, J. Phys. Soc. Japan **18**, 364-8 (1963).

From matrix isolation and gas phase infrared studies, E. Catalano, R. H. Sanborn and J. W. Frazer, J. Chem. Phys. **39**, 2265 (1963), have suggested possible uncertainties in the assignment of the bending mode frequencies in the region from 1630 to 740 cm.⁻¹. The question hinges on the uncertain existence of a gas phase fundamental at about 1600 cm.⁻¹ as observed by P. A. Diguere and I. D. Liu, J. Chem. Phys. **20**, 136 (1952). No corresponding matrix band was found and the gas phase band appeared to be due to absorption on the cell windows. A vapor phase Raman frequency at 1564 cm.⁻¹ was observed, however, by Yu. I. Kotov and V. M. Tatevskii, Opt. i Spektroskopiya **15**, 65 (1963). Catalano et al. suggest one assignment based on the uncertain fundamental and a tentative alternative assignment excluding it. The two assignments give entropies that are 0.26 cal. deg.⁻¹ mole⁻¹ lower and 0.12 higher than the third law value. The lower calculated entropy is probably more reasonable, but the higher value could be more easily modified to agree with the third law value. Thus the alternative assignment was adopted with ν_{11} arbitrarily increased from ~810 to 835 cm.⁻¹.

The structural constants are based primarily on the electron diffraction study of Y. Morino, T. Iijima and Y. Murata, Bull. Chem. Soc. Japan **33**, 46 (1960). Related analyses of the infrared fine structure of the torsional frequency (377 cm.⁻¹), A. Yamaguchi, I. Ichihara, T. Shimomouchi and S. Mizushima, Spectrochim. Acta **16**, 1471 (1960), and of the microwave spectra, Kasuya and Kojima, loc. cit., are in close agreement. The microwave data give an H-H angle of 106° and a torsional angle of 90°2'. Principal moments of inertia of the adopted structure are I_A = 0.574 X 10⁻³⁹, I_B = 3.573 X 10⁻³⁹ and I_C = 3.563 X 10⁻³⁹ g.² cm.²

 Product of Moments of Inertia $I_{AB} I_C = 0.84659 \times 10^{-117} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation, $\Delta H_f^\circ 298.15$ was determined by S. Gunn and L. Greene, J. Phys. Chem. **65**, 773 (1961). A value of 7.8 kcal. mole⁻¹ was selected by J. S. Gordon, Thiel Chemical Corp., Reaction Motors Division, Denville, N. J., "Thermodynamic Data for Combustion Products", January, 1960.

Heat Capacity and Entropy. Molecular constants were taken from J. S. Gordon, op. cit., G. Janz and Y. Mikawa, Bull. Chem. Soc. Japan, **34**, 1495 (1961) reported slightly different values for the vibrational levels.

MERCURY (Hg)

(REFERENCE STATE)

MOL. WT. = 200.61

The reference state is chosen as follows:

0° to 234.29°K Crystal

234.29° to 629.73°K Liquid

629.73° to 800°K Ideal Gas

$$S^{\circ}_{298.15} = 18.171 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 234.29^{\circ}\text{K}$$

$$T_b = 629.73^{\circ}\text{K}$$

$$\Delta H^{\circ}_V 298.15 = 14.652 \pm 0.015 \text{ kcal. mole}^{-1}$$

$$\Delta H^{\circ}_m = 0.5486 \pm 0.0001 \text{ kcal. mole}^{-1}$$

$$\Delta H^{\circ}_V 629.73 = 14.133 \pm 0.020 \text{ kcal. mole}^{-1}$$

Heat Capacity.

The heat capacities of F. L. Smith and N. M. Wolcott, *Phil. Mag.* **1** (8), 854 (1956), 1.2°-20.2°K. R. H. Buey and W. P. Giauque, *J. Am. Chem. Soc.* **75**, 806 (1953), 15°-350°K. and T. B. Douglas, A. P. Ball, and D. C. Ginnings, *J. Research Natl. Bur. Standards*, **46**, 334 (1951), 300°-770°K. have been smoothly joined. There is fair agreement between the selected values and those of G. L. Fickard and F. E. Simon, *Proc. Phys. Soc. A61*, 1 (1948), L. O. Carpenter and P. H. Oakley, *Phil. Mag.* **12**, 511 (1931), L. O. Carpenter and L. O. Stoodley, *Phil. Mag.* **10**, 249 (1930), E. Cohen, O. I. Krulshner, and A. L. Moenvald, *Z. phys. Chem.* **A86**, 437 (1920), A. L. Dixon and W. H. Rodenbush, *J. Am. Chem. Soc.* **49**, 1162 (1927), F. Simon, *Z. phys. Chem.* **107**, 282 (1923), *Ann. Physik* **68**, 241 (1922), J. N. Brønsted, *Z. Elektrochem.* **19**, 714 (1912), and F. Pollitzer, *Z. Elektrochem.* **17**, 5 (1911).

Melting Data.

From Buey and Giauque, loc. cit.

Boiling Point and Heat of Vaporization.

Calculated from the vapor pressures determined by K. D. Carlson, R. J. Thorn, and P. W. Gilles, private communication, October 1961, F. M. Ernberger and H. W. Fitman, *Rev. Sci. Instrum.* **25**, 584 (1954), F. H. Spedding and J. L. Dye, *J. Phys. Chem.* **59**, 561 (1955), and J. A. Beattie, B. E. Blaisdell, and J. Kaminsky, *Proc. Am. Acad. Arts Sciences* **71**, 375 (1937). Earlier measurements are less accurate and have not been used. Gas imperfection has been allowed for by the method of Buey and Giauque, loc. cit.

MERCURY MONIODIDE (HgI)

(IDEAL GAS)

Ground State Configuration ²2

ΔH_f^o 298.15 = 31.9 ± 1.1 kcal mole⁻¹

S_{298.15} = 67.068 cal deg⁻¹ mole⁻¹

Electronic Level and Multiplicity

$\frac{E, \text{ cm}^{-1}}{0}$ $\frac{g_i}{2}$

$\omega_e \nu_e = 1.00 \text{ cm}^{-1}$

$\sigma = 1$

$\alpha_e = [0.0003] \text{ cm}^{-1}$

$r_e = [2.49] \text{ \AA}$

Heat of Formation

K. Wieland and A. Herzog, Helv. Chim. Acta, **32**, 889 (1949) gave 8.3 ± 1.1 kcal for the heat of dissociation into gaseous atoms.

Heat Capacity and Entropy

Vibrational constants were taken from K. Wieland, Zeits. f. Elektrochemie **54**, 761 (1960). Rotational constants were estimated using equation III 123, p. 108, G. Herzberg, "Spectra of Diatomic Molecules," van Nostrand, New York 1950. The bond length was estimated to be 0.985 of the mercuric bond length by analogy with the mercury chlorides.

MERCURY DIIODIDE (HgI₂)

(Crystal)

Mol. Wt. = 454.43

ΔH_f° 298.15 = -25.2 ± 0.4 kcal. mole⁻¹

$S_{298.15}^\circ$ = [43.336] ± 1.5 cal. deg.⁻¹ mole⁻¹

T_c = 402°K

ΔH_t° = 0.601 ± 0.04 kcal. mole⁻¹

T_m = 530°K

ΔH_m° = 4.533 ± 0.05 kcal. mole⁻¹

Heat of Formation. Taken from National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties", (1952).

Heat Capacity and Entropy. The heat capacity was calculated from the heat content data of M. Guinchant, Comp. Rend. 89, 145 (1907) and R. Ewald, Ann. d. Physik (4) 44, 1213 (1914). The entropy was estimated by adjusting its value to provide the best fit of the melting, sublimation and vaporization phenomena.

Transition. The heat and temperature of transition were taken from National Bureau of Standards Circular 500 (loc. cit.).

Melting. The heat of melting was taken from M. Guinchant (loc. cit.), the temperature of melting from National Bureau of Standards Circular 500 (loc. cit.).

Mercury Diiodide (HgI₂)

(Liquid) Mol. Wt. = 454.43

MERCURY DIIODIDE (HgI₂)

(Liquid)

Mol. Wt. = 454.43

ΔH_f^o 298.15 = [-20.862] ± 0.45 kcal. mole⁻¹

ΔF_f^o 298.15 = [51.544] ± 1.5 cal. deg.⁻¹ mole⁻¹

T_m = 530°K

ΔH_m = 4.553 ± 0.05 kcal. mole⁻¹

T_b = 627°K

ΔH_v = 14.141 ± 0.25 kcal. mole⁻¹

Heat of Formation. Calculated from ΔH_f^o 298(c).

Heat Capacity and Entropy. Heat capacity measurements were obtained from the data of M. Guinchant, Comp. Rend. SG, 145 (1907) in the range 540-600°K and were assumed constant above and below this range. A glass type transition was assumed at 353°K below which the heat capacity was that of HgI₂(c). The entropy was calculated from the entropy of the crystal and the measured entropy of fusion.

Fusion and Vaporization. T_m and T_b are taken from National Bur. of Standards (U.S.) Circular 500 (1952). ΔH_m is from the data of M. Guinchant (loc. cit.) and ΔH_v was obtained from the data of E. B. R. Pridoux, J. Chem. Soc. (London) 97, 2032 (1910) and F. M. G. Johnson, J. Amer. Chem. Soc. 33, 777 (1911).

Heat of Formation. The heat of formation of the crystal as given in National Bureau of Standards (U.S.) Circular 500, "Selected Values of Chemical Thermodynamic Properties", 1952 was combined with the 3rd law heat of sublimation at 298°K derived from the data of K. Niwa and Z. Shibata, J. Pac. Sci. Hokkaido Imp. Univ. Ser. III 2, 183 (1939); D. W. Magee, Univ. Microfilms No. 14474 Ann Arbor, Mich., and F. M. G. Johnson, J. Amer. Chem. Soc. 53, 777 (1931).

Heat Capacity and Entropy. The vibrational constants were given by W. Klemperer and L. Lindeman, J. Chem. Phys. 25, 397 (1956). The anti-symmetric stretching frequency was estimated by analogy with the bromide and chloride. The bond length was an average of the values given by H. Braune and S. Knoke, Naturwiss. 21, 349 (1933); A. H. Gregg, G. C. Hampson, G. I. Jenkins, P. L. F. Jones and L. E. Sutton, Trans. Farad. Soc. 33, 852 (1937) and P. A. Akshin, V. P. Spiridonov and A. N. Khodachenkov, Zhur. Fiz. Khim. 35, 20 (1959).

MERCURY MONOXIDE (HgO)

(CRYSTAL)

MOL. WT. = 216.61

$$\Delta H_f^0 298.15 = -21.699 \pm 0.024 \text{ kcal. mole}^{-1} \quad S_{298.15}^0 = 16.795 \pm 0.03 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_{\text{decomp}} = 749^\circ\text{K.}$$

Heat of Formation.

Obtained from the entropy obtained by T. W. Bauer and H. L. Johnston, J. Am. Chem. Soc. 75, 2217 (1953) and the free energy of formation as determined from the numerous cell measurements described by Bauer and Johnston. The value adopted for $\Delta F_f^0 298.15$ was $-42,707 \pm 14 \text{ cal. mole}^{-1}$.

Heat Capacity and Entropy.

The heat capacity has been measured from 15° to 298°K. by Bauer and Johnston loc. cit. The extrapolation below 15°K was done assuming a T^3 law and gave $S_{15}^0 = 0.264 \text{ e.u.}$ Above 298° the data was extrapolated smoothly and adjusted to give the observed decomposition vapor pressures of G. B. Taylor and G. A. Rullett, J. Phys. Chem. 17, 565 (1913).

Decomposition.

According to Taylor and Rullett, loc. cit., the vapor pressure reaches 1.89 atmospheres at 749°K. This corresponds to the decomposition to 2 Hg(g) + O₂(g), the equilibrium constant being unity at 1.89 atm.

MERCURY MONOXIDE (HgO)

(IDEAL GAS)

GFW = 216.5894

Ground State Configuration ¹IΔH_{f,0}^o = [11] kcal/molS_{298.15}^o = [57] gibbs/molΔH_{f,298.15}^o = [10] kcal/mol

Electronic Levels and Quantum Weights

E _i , cm ⁻¹	g _i
0	1

ω₀X_e = [680] cm⁻¹ω₀X_e = [4.7] cm⁻¹

σ = 1

B_e = [0.336] cm⁻¹r_e = [1.84] Å

Heat of Formation

The heat of formation (ΔH_{f,298}^o) of HgO(g) is estimated to be 10 ± 15 kcal/mol. This value is obtained from the heat of formation of PbO(g) and comparison of the heats of formation of analogous lead and mercury compounds using the method of Karapet'yants (1). The corresponding dissociation energy (D₀) of HgO(g) is 64 ± 15 kcal/mol.

Heat Capacity and Entropy

The equilibrium internuclear separation (r_e) of HgO(g) is estimated from the corresponding quantity for PbO(g) and comparison of Hg-X and Pb-X bond distances for cases in which values of both distances are known. The rotational constant B_e is calculated from r_e. The fundamental vibrational frequency ω₀ is estimated from Guggenheimer's relation for multiple bonded molecules (2). The anharmonic vibrational term ω₀X_e is calculated from ω₀(4ω₀ + 2ω_e). The value of ω₀ is calculated from the Morse potential function. The ground state configuration is estimated from the building-up principle (3), the united atom theory (3), and from analogy with BeO.

 $\Delta H_f^\circ 298.15 = -28.462 \pm 0.5 \text{ kcal. mole}^{-1}$
 $S^\circ 298.15 = 57.670 \pm 2.0 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 563^\circ\text{K}$
 $\Delta H_m = [6.5] \pm 2.0 \text{ kcal. mole}^{-1}$

Heat of Formation. The average value of the cell measurements of W. C. Vosburgh, J. Amer. Chem. Soc. 50, 2386 (1928); E. Cohen Zeits. f. physik. Chemie 94, 210 (1920); T. Yoshida, J. Chem. Soc. Japan 48, 435 (1927); L. W. Øholm, Acta. Soc. Scientiarum Fennicae 41, 1 (1913) and the calorimetric values of R. Varot, Ann. Chim. Phys. (7) 9, 91 (1896) and W. Nernst, Zeits. f. Physik. Chemie 2, 23 (1888) was adopted.

Heat Capacity and Entropy. The heat capacity at 298.15° was taken from National Bureau of Standards (U.S.) Circular 500 (1952) and was estimated above this by analogy with mercurous chloride. The entropy was obtained from the heat and free energy of formation obtained from the cell measurements listed under heat of formation.

Melting. P. Yvon, Comp. Rend. 76, 1607 (1873) gives 563°K for the melting point. The heat of melting was estimated by assuming the entropy of melting per atom to be the same as that for mercuric iodide.

March 31, 1962

MERCURY MONIODIDE, DIMERIC (Hg_2I_2) (Liquid)

Mol. Wt. = 655.04

ΔH°_f 298.15 = [-23.021 ± 2.5] kcal. mole⁻¹

$S^\circ_{298.15}$ = [66.868 ± 8.0] cal. deg.⁻¹ mole⁻¹

T_m = 563°K

ΔH°_m = [6.5 ± 2.0] kcal. mole⁻¹

T_b = [630]°K (decomp.)

Heat of Formation. Calculated from ΔH°_f (crystal) and the estimated heat of melting and heat capacity.

Heat Capacity and Entropy. C_p was estimated as 1.33 times the heat capacity of mercuric iodide. The entropy was calculated from S° crystal, the estimated ΔH°_m and the heat capacities of solid and liquid.

Melting and Vaporization. The melting point was given by P. Yvon, Comp. Rend. 76, 1607 (1873); the heat of melting was estimated from that of mercuric iodide, by assuming the entropies of melting per atom to be equal. Mercurous iodide decomposes to $\text{Hg}(g)$ and $\text{HgI}_2(g)$ at the boiling point which was estimated from the free energy change of the reaction.

Thermodynamic Functions.

Atomic constants were taken from G. E. Moore [U. S. Natl. Bur. Standards Circ. 467, Vol. III (1958)]. The higher levels were averaged. Calculated thermodynamic functions are in good agreement with those of W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards, 55, 147 (1955)].

Heat of Formation.

The dissociation energy of diatomic iodine is given as D₀⁰ = 12452.5 ± 1.5 cm.⁻¹ by R. D. Verma [J. Chem. Phys. 32, 738 (1960)]. Converting to calories and combining with the heat of sublimation of iodine yields the heat of formation of the ideal monatomic gas. Evans, Munson, and Wagman [loc. cit.] list several investigations of the dissociation energy from equilibrium data. These are all less precise than the spectroscopic value and are not given any weight. The "best" average of the thermal data yields D₀⁰ = 35.568 kcal. mole⁻¹ (spectroscopic = 35.606 kcal. mole⁻¹).

$\Delta H_f^\circ = -78.14 \pm 0.1$ kcal/mol	$\Delta H_f^\circ = -78.37 \pm 0.1$ kcal/mol
$\Delta H_{298.15}^\circ = -78.37 \pm 0.1$ kcal/mol	$\Delta H_{298.15}^\circ = -78.37 \pm 0.1$ kcal/mol
$\Delta H_m^\circ = 5.74$ kcal/mol	
$\Delta H_{298.15}^\circ$ (to monomer) = 48.37 kcal/mol	
$\Delta H_{298.15}^\circ$ (to dimer) = 55.84 kcal/mol	

Heat of Formation

The heats of solution of KI(c) have been critically reviewed by V. B. Parker, U. S. Natl. Bur. Std. NBS-RS-2, 1965. Six pertinent results are quoted in the table below. Adopting the best value, $\Delta H_{298}^\circ = 4.86 \pm 0.03$ kcal/mol, reported by Parker, and $\Delta H_f^\circ = -60.32$ and -13.19 kcal/mol for K^+ (H_2O) and I^- (H_2O), respectively, obtained from U.S. Natl. Bur. Std. Tech. Note 270-1, 1965, we obtain ΔH_{298}° (KI, c) = -78.37 ± 0.1 kcal/mol, which is adopted.

ΔH_f° , kcal/mol*	Temperature, °C	n**	Investigator
4.830 \pm 0.05	19	200	J. Thomsen, Thermochemische Untersuchungen, J. Barth Verlag, Leipzig, 1882-86.

5.020	24.5	18.5	M. Bobtelsky and R. D. Lairech, J. Chem. Soc. 1950, 3612 (1950).
4.830 \pm 0.07	25	75000	A. F. Kapustinskii and S. I. Drakin, Zhur. Fiz. Khim. 28, 581 (1952).

*Values are adjusted to 298.15°K and to infinite dilution.

**n is the number of moles of H_2O per mole of KI(c) in solution.

Heat Capacity and Entropy

The low temperature heat capacities are based on those measured by W. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) A242, 467 (1957), 2.86 - 268.0°K. The adopted values are in good agreement with the Cp values reported by W. W. Scallies, Phys. Rev. 112, 49 (1958), 2 - 7°K. The data of K. Clusius, J. Goldmann, and A. Perlick, Z. Naturforsch. 4A, 424 (1949), 10.27 - 269.9°K, appear to be too low in the temperature range 70 - 270°K and are not used. Low temperature enthalpies, 83 - 273°K, have been measured by F. Koref, Ann. Physik 2, 49 (1911). The value of S_{298}° is derived based on the adopted low temperature heat capacities, using $S_{298}^\circ = 0.0033$ eu.

The high temperature enthalpies were determined by S. M. Skuratov and S. A. Lapushkin, Russ. J. Gen. Chem. (English Transl.) 21, 2485 (1951), 623 - 923°K; A. S. Dworin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tenn., Dec. 1, 1964, 854 - 954°K; and C. B. Cooper, J. Chem. Phys. 21, 777 (1953), 297 - 973°K. Heat Capacities are derived from the enthalpies by a curve fitting method which requires a smooth joint with the low temperature Cp. Enthalpy values used in the curve fit include smooth values calculated from the equation of Skuratov and the value $H_{954}^\circ - H_{298}^\circ = 9.2$ kcal/mol from Dworin. Deviation of the input values from the selected enthalpies are all less than 0.3 percent, while the deviations of the data of Cooper range from ± 1.0 percent at 570°K to -1.6 percent at 974°K. Since the latter point is 20° above the melting point, there appears to be an error in Cooper's measurement of temperature. Cp above the melting point is obtained by graphical extrapolation.

Melting Data

Tm has been reported to be 953, 952 and 954°K by R. C. Ray and V. Dayal, Trans. Faraday Soc. 32, 741 (1936); T. E. Phipps and E. G. Partridge, J. Am. Chem. Soc. 51, 1331 (1929); and J. W. Johnson and M. A. Bredig, J. Phys. Chem. 52, 604 (1958), respectively. The last value is adopted. The heat of melting was determined by A. S. Dworin and M. A. Bredig, J. Phys. Chem. 54, 269 (1960), using drop calorimetry.

Heat of Sublimation

The difference between ΔH_{298}° for KI(g) and KI(c) is ΔH_{298}° (to monomer). The ΔH_{298}° (to dimer) is calculated as the enthalpy change for the following reaction: $2KI(c) = K_2I_2(g)$.

POTASSIUM IODIDE (KI)

(LIQUID)

GFW = 166.0064

$$S_{298.15}^{\circ} = 27.273 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = -74.771 \text{ kcal/mol}$$

$$T_m = 954^{\circ}\text{K}$$

$$\Delta H_m^{\circ} = 5.74 \text{ kcal/mol}$$

$$\Delta H_v^{\circ} = 45.62 \text{ kcal/mol}$$

Heat of Formation

The heat of formation, ΔH_{298}° , is obtained from ΔH_{298}° (KI, c) by adding ΔH_m° and the difference between $H_{954}^{\circ} - H_{298}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy

The heat capacity is derived as 17.3 gibbs/mol from the enthalpy measurements, 954 - 1014°K, by A. S. Dworkin, private communication, Oak Ridge National Laboratory, Oak Ridge, Tenn., Dec. 1, 1984. This Cp value is adopted in the temperature range 298 - 2500°K. S_{298}° is obtained in a manner analogous to that of the heat of formation.

Melting Data

See KI(c) table for details.

Vaporization Data

The boiling point, Tb = 1618°K, is calculated as the temperature at which the sum of the partial pressures of KI(g) and $K_2I_2(g)$ over KI(l) equals one atmosphere. The value of ΔH_v° is calculated as the heat required to produce one mole of vapor mixture, which contains 78 percent monomer (KI) and 22 percent dimer (K_2I_2) at Tb.

Tb was reported as 1603 and 1590 K by H. von Wartenberg and P. Albrecht, Z. Elektrochem. 21, 162 (1921), and O. Ruff and S. Mugdan, Z. Anorg. Chem. 117, 147 (1921), respectively.

Heat of Formation

The heat of formation is derived from the sublimation and vaporization data analyzed below. Many investigators have determined the total pressures of KI(g) and KI₂(g) over KI(s) or KI(l) by static methods or "apparent" pressures by Knudsen effusion or transpiration. These pressures are converted to monomer pressures by use of functions [see K₂I₂(g) table] which are consistent with the dimer-monomer equilibrium data of Batz (3). Second and third law analyses of the monomer pressures show reasonable agreement. The selected value of ΔH_f⁰₂₉₈ = -30.0 ± 0.5 kcal/mol is also in good agreement with -30.23 ± 1.15 and -30.46 kcal/mol derived from D₀⁰ = 3.32 ± 0.05 and 3.33 eV reported by Gaydon (12) and Herzberg (11), respectively.

** (A) KI(c) = KI(g); (B) KI(l) = KI(g)

Heat Capacity and Entropy

The ground state configuration is obtained from Herzberg (11). The adopted values of ω_e , $\omega_e x_e$, B_e , a_e , and r_e were determined using millimeter wave molecular beam spectroscopy by Rusk and Gordy (12), and corrected to the average isotopic species. Similar values were reported by Honig et al. (13) from microwave spectra, except ω_e which was given as 193.74 cm⁻¹. The value of ω_e was derived to be 200 and 173 cm⁻¹ by Barrow and Caunt (14) and Rice and Klemperer (15). The moment of inertia is 4.5979 x 10⁻³⁸ g cm².

LITHIUM IODIDE (LiI)

(CRYSTAL)

GFW = 133.8434

ILI

 $\Delta H^\circ_f = \text{Unknown}$ $\Delta H^\circ_{298.15} = -64.55 \pm 0.1 \text{ kcal/mol}$ $\Delta H^\circ_m = 3.50 \text{ kcal/mol}$ $S^\circ_{298.15} = [20.5] \text{ gibbs/mol}$ $T_m = 742^\circ \text{K}$

Heat of Formation.

The heat of formation, $\Delta H^\circ_{298}(\text{LiI}, c) = -64.55 \text{ kcal/mol}$, was calculated from the heat of solution of lithium iodide (c) at infinite dilution and the ionic heats of formation of $\text{Li}^+(\text{COOH}_2\text{O})$ and $\text{I}^-(\text{COOH}_2\text{O})$.

V. B. Parker, "Thermal Properties of Aqueous Uni-univalent Electrolytes," NSRDS-NBS 2, Apr. 1, 1965, reviewed the literature heat of solution data and gave the "best" value, $\Delta H^\circ_{298}(\text{Li}^+\text{COOH}_2\text{O}) = -15.130 \pm 75 \text{ cal/mol}$ for $\text{LiI}(c) \rightarrow \text{LiI}(\text{COOH}_2\text{O})$ at 298.15°K . The ionic heat of formation, $\Delta H^\circ_{298}(\text{I}^+\text{COOH}_2\text{O}) = -66.49 \text{ kcal/mol}$, was calculated from $\Delta H^\circ_{298}(\text{LiOH}\cdot\text{COOH}_2\text{O}) = -121.46 \text{ kcal/mol}$ (see JANAF $\text{LiOH}(c)$ Table, Mar. 31, 1966) with $\Delta H^\circ_{298}(\text{OH}^-\text{COOH}_2\text{O}) = -54.97 \text{ kcal/mol}$ from NBS Technical Note 270-1, "Selected Values of Chemical Thermodynamic Properties," Oct. 1, 1965. The value $\Delta H^\circ_{298}(\text{I}^-\text{COOH}_2\text{O}) = -13.19 \text{ kcal/mol}$ was also obtained from NBS Technical Note 270-1. Combination of the ionic heats of formation of $\text{Li}^+(\text{COOH}_2\text{O})$ and $\text{I}^-(\text{COOH}_2\text{O})$ gives the heat of formation of $\text{LiI}(\text{COOH}_2\text{O})$, $\Delta H^\circ_{298} = -79.68 \text{ kcal/mol}$.

Heat Capacity and Entropy.

A. S. Dworin, private communication, Oak Ridge National Laboratory, Dec. 1964, has measured the enthalpy changes by the drop method ($642\text{--}802^\circ \text{K}$), yielding ($H^\circ_{42} - H^\circ_{298}$) = 6.0 kcal/mol for the crystal at the melting point. Heat capacities derived from his data were $C_p 692^\circ = 14.8$ and $C_p 772 = 15.1 \text{ cal/deg-mol}$ for the crystal and liquid, respectively. The tabulated heat capacities were estimated based on these values and on the heat capacities of $\text{LiCl}(c)$, $\text{NaCl}(c)$ and $\text{NaI}(c)$.

The entropy, $S^\circ_{298.15} = 20.5 \text{ eu}$, was estimated by adding the entropy difference between $\text{NaI}(c)$ and $\text{NaCl}(c)$ to the entropy of lithium chloride (c) at 298.15°K . Comparisons with other alkali halides give results within $\pm 0.5 \text{ eu}$ of this value.

K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960), 592 (1961), has estimated the heat capacities ($C_p = 12.30 + 2.44 \times 10^{-3} T \text{ gibbs/mol}$) and the entropy ($S^\circ_{298} = 17.50 \text{ eu}$).

Melting Data.

The selected heat of fusion ($\Delta H^\circ_{298} = 3.50 \text{ kcal/mol}$) was obtained from enthalpy measurements in a drop calorimeter by A. S. Dworin and M. A. Bredig, J. Phys. Chem. 64, 269 (1960).

LITHIUM IODIDE (LiI)

(LIQUID)

GFW = 133.8434

 $\Delta H^\circ_{298.15} = [23.568]$ gibbs/mol $\Delta H^\circ_{298.15} = -61.749$ kcal/mol $\Delta H^\circ_{\text{m}} = 3.50$ kcal/mol ΔH° (to equilibrium mixture) = 23.3 kcal/mol ΔH° (to monomer only) = [32.6] kcal/mol $T_m = 742^\circ\text{K}$ T_b (to equilibrium mixture) = 1449°K T_b (to monomer only) = [1497]°K

Heat of Formation.

The heat of formation was calculated from that of the crystal by adding the heat of fusion and the difference between $H^\circ_{742} - H^\circ_{298}$ for crystal and liquid.

Heat Capacity and Entropy.

A. S. Dworin, private communication, Oak Ridge National Laboratory, Dec. 1964, has derived the heat capacity, $C_p = 15.1$ gibbs/mol, from enthalpy measurements, $742 - 802^\circ\text{K}$, by the drop method. The liquid heat capacity was assumed to be a constant, 15.1 gibbs/mol. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See LiI(c) table for detail.

Vaporization Data.

T_b (to monomer only) is determined as the temperature at which the Gibbs energy change (ΔG°) for the reaction $\text{LiI(l)} = \text{LiI(g)}$ approaches zero. The corresponding enthalpy change (ΔH°) at boiling point is the heat of vaporization ΔH°_v (to monomer only).

T_b (to equilibrium mixture) is the temperature at which the sum of the calculated partial vapor pressures of LiI(g) and $\text{Li}_2\text{I}_2(\text{g})$ reaches one atmosphere (trimer and higher polymer have been neglected in calculation). This value is in good agreement with the boiling point of 1444°K from the least squares fit of the total vapor pressure data measured by O. Ruff and S. Mugdan, Z. anorg. Chem. **117**, 147 (1921). ΔH°_v (to equilibrium mixture) at the boiling point is calculated as the heat of vaporization of one mole of liquid to vapor containing 30.44 mole percent of dimer. For detailed information see LiI(g) and $\text{Li}_2\text{I}_2(\text{g})$ tables.

Heat of Formation.

The heat of formation (ΔH_{f298} (LiI, g) = -21.75 ± 2 kcal/mol) was calculated from the selected heat of sublimation and the heat of formation for lithium iodide (c). The heat of sublimation has been determined mass-spectrometrically from the ion intensity measurement (2nd law method) by L. N. Gorokhov, Dokl. Akad. Nauk SSSR 142, 113 (1962), as ΔH_s⁰ (to monomer) = 42.9 ± 0.6 and ΔH_s⁰ (to dimer) = 43.2 ± 0.4 kcal/mol in the temperature range from 626-722°K. Gorokhov also reported the partial vapor pressure of monomeric lithium iodide (P_{monomer} = 3 X 10⁻³ mm Hg) and the ratio of dimer to monomer (P_{dimer}/P_{monomer} = 6) which have been used for third law calculation. Using the same technique, L. Friedman, J. Chem. Phys. 23, 477 (1955), reported the heats of sublimation as ΔH_s⁰ (to monomer) = 41.9 ± 0.5 and ΔH_s⁰ (to dimer) = 40.8 ± 0.5 kcal/mol in the temperature range from 630° to 730°K. J. Berkowitz, H. A. Tammann and W. A. Chupka, J. Chem. Phys. 36, 2170 (1962) have also studied the lithium iodide vapor in the mass spectrometer and reported the second law and third law values of the heat of dimerization at 800°K as 37.9 and 40.4 kcal/mol, respectively. Using the JANAF thermodynamic functions, all the heats of sublimation and dimerization at different temperatures have been reduced to 298°K and summarized in the following table. The total vapor pressure over the liquid has been measured by a boiling point method in the temperature range 1223° to 1413°K by O. Ruff and S. Muggen, Z. anorg. Chem. 117, 147 (1921). (Their data have been quoted by H. von Wartenberg and H. Schulz, Z. Elektrochem. 27, 568 (1921).) In order to have good agreement between the calculated vapor pressure and the observed total vapor pressure, the heats of sublimation have been so chosen as ΔH_s⁰ (to monomer) = 42.8 kcal/mol and ΔH_s⁰ (to dimer) = 42.6 kcal/mol and the heat of dissociation of dimer, ΔH_d⁰ = 43.0 kcal/mol. The calculated boiling point (to equilibrium mixture) is 1449°K which agrees with 1443°K reported by Wartenberg and Schulz, and also 1462°K by Ruff and Muggen.

Heat Capacity and Entropy.

The bond distance and the rotational constants (B_e and α_e), corrected to the isotopic abundance of 7.4% Li⁶ and 92.6% Li⁷, were obtained from the microwave studies by A. Honig, M. Mandel, M. L. Stiche and C. H. Townes, Phys. Rev. 96, 629 (1954). The vibrational constants (ω_e and ω_ex_e) were determined from the infrared spectrum by W. Klemperer, W. G. Norris, A. Buchler and A. O. Emalle, J. Chem. Phys. 33, 1534 (1960).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by R. L. Wilkins, J. Chem. Eng. Data 5, 337 (1960), who used slightly different molecular constants.

Bond Distance: O-N = [1.15] Å

N-I = [2.3] Å

Bond Angle: O-N-I = [120]°

Product of the Moment of Inertia: $I_A I_B I_C = [7.742 \times 10^{-115}] \text{ g}^3 \text{ cm}^6$

Heat of Formation.

The heat of formation (ΔH_f°) for INO (g) is estimated by comparison with those for FNO(g), ClNO(g), BrNO(g), and the related cyanogen halides.

Heat Capacity and Entropy.

The molecular structure and bond angle are estimated by comparison with those for ClNO(g) and BrNO(g). The N-O bond distance is assumed to be the same as that in NO(g). The N-I bond distance (r_{N-I}) is calculated based on an assumption that $r_{ON-Cl} - r_{ON-I} = r_{Cl-I} - r_{I-I}$. The vibrational frequencies are estimated by comparison with those for FNO(g), ClNO(g) and BrNO(g). The three principal moments of inertia are: $I_A = 8.834 \times 10^{-40}$, $I_B = 2.916 \times 10^{-38}$ and $I_C = 3.005 \times 10^{-36} \text{ g cm}^2$.

- $$-68.80 \pm 0.2$$

Heat Capacity and Entropy.

Smoothed heat capacities between 3° and 270°K. have been presented by M. T. Berg and J. A. Morrison, Proc. Roy. Soc. (London) **242A**, 467 (1957). Above 270°K. the heat capacity was obtained by comparing with KI(c) on a reduced temperature plot of C_p/T versus T. The values so obtained were increased by 1.4% to bring them into line with the low temperature data.

Melting Data.

A. Dworkin and M. Bredig, J. Phys. Chem. **64**, 269 (1960) have measured both T_m and ΔH_m .

Sept. 30, 1963

S_{298.15} = 28.862 cal. deg.⁻¹ mole⁻¹
 T_m = 933°K.
 T_b = 1577°K. (equilibrium mixture)

ΔH_f^o 298.15 = -63.695 kcal. mole⁻¹ΔH_m = 5.64 kcal. mole⁻¹

Heat of Formation.

ΔH_f^o 298.15 was calculated from the heat of formation of the crystal plus the heat of melting and the difference between H₉₃₃-H₂₉₈ for crystal and liquid.

Heat Capacity and Entropy.

C_p was estimated assuming each atom contributed 7/5 cal. deg.⁻¹ mole⁻¹. S_{298.15} was calculated in a manner similar to ΔH_f^o 298.15.

Melting Data.

See table for crystal.

Vaporization Data.

The boiling point is that given by K. K. Kelley, U. S. Bureau of Mines Bulletin 363, 1955 from examination of the high temperature vapor pressure.

Lead Moniodide (PbI)

Mol. Wt. = 334.12

ΔH_f⁰ 298.15 = 25.7 ± 9.2 kcal. mole⁻¹

S_{298.15} = 66.855 cal. deg.⁻¹ mole⁻¹

Ground State Configuration ²Π_{1/2}

Electronic Levels and Multiplicities

E, cm. ⁻¹	g _i
0	2
[8000]	2

ω_e = 160.5 cm.⁻¹

ω_ex_e = 0.25 cm.⁻¹

B_e = [0.02940] cm.⁻¹

α_e = [0.00000] cm.⁻¹

σ = 1

Heat of Formation. ΔH_f⁰ 298.15 was calculated from the dissociation energy of PbI(g) reported by A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, Ltd., London, 1953.

Heat Capacity and Entropy. Ground state configuration, ω_e and ω_ex_e were obtained from G. Herzberg, "Spectra of Diatomic Molecules," Van Nostrand, New York, 1950. B_e and α_e were estimated by comparison with the corresponding values for the other diatomic halide molecules. Electronic levels and multiplicities were estimated from those for PbF(g).

Titanium Moniodide (TiI)
(Ideal Gas) GFW = 174.8044

TITANIUM MONIODIDE (TiI)

GFW = 174.8044

Ground State Configuration [⁴F]

(IDEAL GAS)

$$\Delta H_f^\circ = [65.8 \pm 10.0] \text{ kcal/mol}$$

$$\Delta H_{298.15}^\circ = [65.5 \pm 10.0] \text{ kcal/mol}$$

Heat of Formation

The heat of formation, ΔH_f° , of TiI (g) is calculated from the dissociation energy, D_0° , which is estimated as 73 kcal/mol. This estimate is obtained from the relation $D(\text{TiI}_2) < D(\text{TiI}) < D(\text{TiI}_3)$, where D represents the average energy per bond, which is valid for the titanium fluorides. The dissociation energy of TiF(g) from which the relation is derived was estimated relative to that of TiF₂(g) by Zmbov and Margrave (1).

Heat Capacity and Entropy

The vibrational frequency, ω_e , and the anharmonic vibrational term, $\omega_e x_e$, are estimated from those of TiCl(g) and comparisons of the mercury and alkali monohalides. The interatomic distance is estimated from Guggenheimer's relation (2). B_e is calculated from r_e . The ground state term and electronic levels are estimated from the ground state multiplet of Ti⁺ (3). α_e is estimated from the Morse potential function.

Heat of Formation

The dissociation energy was estimated from a correlation of the JANAP values for TiCl(g), TiI(g), and ZrCl(g). The resulting value, 29.7 kcal. mole⁻¹, was employed with auxiliary JANAP heats of formation for Zr(g) and I(g) in calculating ΔH_f^o 298.15°

Heat Capacity and Entropy

The vibrational frequency was estimated from those of TiI(g), TiCl(g), and the alkali halides. The ground state configuration was assumed to be analogous to the ground term of TiCl(g) as given by E. A. Shenoy, et al., Optics and Spectroscopy, 12, 359 (1962). The internuclear distance was estimated from those of TiBr(g), TiI(g) and ZrI(g).

September 30, 1961

IODINE (I₂)

(REFERENCE STATE)

MOL. WT. = 253.82

0°K to 366.75°K Crystal
366.75°K to 458.59°K Liquid
458.59°K to 8000°K Ideal Diatomic Gas

Heat of Formation.

Zero by definition.

Heat Capacity of Crystal.

The recent measurements of D. A. Shirley and W. P. Giauque [J. Am. Chem. Soc. 81, 4778 (1959)] over the temperature range 13° to 327°K are adopted, no weight being given to the earlier work of E. Lange [Z. Physik. Chem. 110, 343 (1924)], which deviate by 1% or more. L. G. Carpenter and T. F. Harle [Phil. Mag. 23, 193 (1937)] measured the heat capacity of crystalline and liquid iodine by an adiabatic method. Their data are in poor agreement with Shirley and Giauque in the range 275° to 330°K and are given no weight. K. J. Frederick and J. H. Hildebrand [J. Am. Chem. Soc. 80, 1436 (1958)] measured the enthalpy of crystalline and liquid iodine relative to 298°K by the method of mixtures. For calibration they used a slug of copper. The enthalpy of copper which they used now appears to be too high [K. K. Kelley, U. S. Bur. Mines Bull. 594 (1960)]. The results of Frederick and Hildebrand were corrected by a factor which varied linearly from zero at 300°K to 0.995 at 400°K and 0.990 at 500°K. These corrected enthalpies and the heat capacities of Shirley and Giauque above 298°K were used to derive the equations for crystalline iodine:

$$H_p - H_{298} = -12.1048 T + 0.029505 T^2 - 6.686 \times 10^{-5} T^3 + 3228.65$$

$$C_p = -12.1048 + 0.059012 T + 6.686 \times 10^{-5} T^2$$

Heat Capacity of Liquid, Melting Point, and Heat of Melting.

For the liquid, the corrected results of Frederick and Hildebrand give:

$$H_p - H_{298} = 19.281 T - 2516.5$$

$$C_p = 19.281$$

The melting point given by Frederick and Hildebrand is 113.6°C. The difference in the heat content equations at the melting point gives the heat of melting as 3708.7 cal. mole⁻¹.

Heat of Sublimation, Ideal Gas Functions.

See tables for ideal gases for details.

Iodine (I₂)

$$\Delta H_f^\circ 298 = +3.232 \text{ kcal. mole}^{-1}$$

$$S^\circ 298 = 35.936 \text{ cal. mole}^{-1} \text{ deg.}^{-1}$$

$$\Delta H_m = 3708.7 \text{ cal. mole}^{-1}$$

$$\Delta H_v = 10025.5 \text{ cal. mole}^{-1}$$

$$T_m = 386.75^\circ\text{K}$$

$$T_b = 458.39^\circ\text{K}$$

Heat of Formation.

Obtained as the heat of fusion calculated to 298.15°K by adding H_{386.75}-H_{298.15} for solid and subtracting H_{386.75}-H_{298.15} for liquid.

Heat Capacity.

The liquid heat capacity of 19.281 cal. mole⁻¹ deg.⁻¹ derived from the data of Frederick and Hildebrand (see Reference State) was extrapolated back to 298.15°K and up to 1000°K.

Entropy.

The value at 400°K calculated for the reference state was back calculated to 298.15°K by means of the constant heat capacity of 19.281 cal. mole⁻¹ deg.⁻¹

Vaporization.

See ideal gas tables for details.

IODINE, DIATOMIC (I₂)

MOL. WT. = 253.82

$$\Delta H_{f, 298}^{\circ} = 15.66 \pm .01 \text{ kcal. mole}^{-1}$$

(IDEAL GAS)

$$\Delta H_{f, 298}^{\circ} = 14.924 \text{ kcal. mole}^{-1}$$

$$\text{Ground State} = \sum$$

$$S_{298}^{\circ} = 62.281 \text{ cal. mole}^{-1} \text{ deg}^{-1}$$

$$\omega_e = 214.52 \text{ cm}^{-1}$$

$$\omega_e x_e = 0.6133 \text{ cm}^{-1}$$

$$B_e = 0.037584 \text{ cm}^{-1}$$

$$D_e = 0.455 \times 10^{-8} \text{ cm}^{-1}$$

$$\alpha_e = 0.0001206 \text{ cm}^{-1}$$

$$\sigma = 2$$

Thermodynamic Functions.

The molecular constants are from the work of D. H. Rank and W. M. Baldwin [J. Chem. Phys. **19**, 1210 (1951)] with a revised value of $\omega_e = 214.52$ as given by R. D. Verma [J. Chem. Phys. **32**, 738 (1960)]. The value of $\omega_e x_e$ has been adjusted to allow for the dropping of higher order corrections not used in the computer program. The calculated thermodynamic functions are in good agreement with those of W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards **55**, 147 (1955)], who used very slightly different constants. L. Mathieson and A. L. O. Rees [J. Chem. Phys. **25**, 753 (1956)] give further refinements to the spectroscopic data which are negligible for our purpose. Their ω_e is also slightly low since it is based on Rank and Baldwin.

Heat of Formation.
